Based on Best Management Practices Manual for the Shipbuilding and Repair Industry, The Commonwealth of Virginia State Water Control Board.

FORWARD

There has been increasing concern in recent years about pollutants generated by the shipbuilding and repair industry. In particular, abrasive blast media, metals, metal related compounds, petroleum associated hydrocarbons and antifouling ingredients in paints have come under scrutiny. One reason for concern with pollutants generated by ship repair activities is the close proximity to water and the potential to pollute this resource. Technical inspections and toxics monitoring of shipyard effluent show that significant levels of pollutants are generated by shipbuilding, repair and maintenance operations. Inspections demonstrate a continuing effort by the DEQ to prevent shipyard-related pollutants from entering State waters, particularly to sensitive bays and estuaries.

As a result of these inspections, it was evident that Best Pollution Prevention Practices (BPP's) for the ship and boat repair industry were necessary. In 1993, the DEQ proceeded with the identification of general BPP's applicable to this industry. National Pollutant Discharge Elimination System (NPDES) permits were written to include BPP language, however, the permit wording was later determined to be too general. It was apparent that BPP's were needed that would contain practical hazardous sandblast grit containment methods .

This manual was developed through literature search, yard inspections and discussions between DEQ and the marine industry, and is designed to serve as an introduction to pollution prevention for repair facilities that do abrasive blasting. Implementation of BPP's described herein should provide significant and economical pollution control at boat yard and repair facilities.

Because the Department of Environmental Quality is not responsible for the implementation and maintenance of the BPP's described in this manual, and does not have daily control over each facility's particular use of the BPP's, the Department will not guarantee or warrant the performance or results that may be obtained by the implementation of the BPP's described herein; only that the BPP's will perform substantially in accordance with the specifications and constraints set forth in this manual, assuming they are properly installed and maintained.

BPP's are intended to complement, not substitute, existing Federal and State regulations.

INTRODUCTION

The shipbuilding and repair industry presents a unique problem in terms of applying pollution control techniques. Although a given facility may not compare exactly with another facility in terms of repair capabilities, type and size of docks, and so on, there are enough similarities between facilities to describe pollution control techniques that can be adapted to suit a specific site.

There are several different functions that occur at ship and boat repair facilities. Some facilities employ a few people, while others employ many people, including various

subcontractors, blacksmiths, boilermakers, chemists, carpenters, electricians, laborers, machinists, welders, painters, sandblasters, riggers, pipe fitters and a number of administrative and managerial staff.

Each of these facilities and associated shipyard services create their own unique set of potential environmental concerns. A tremendous amount of spent blast abrasive dust and grit is generated daily. Millions of gallons of vessel discharges are piped, collected, tested, treated, recycled or transported. Air pollution, noise pollution and water pollution can occur simultaneously with the variety of operations that take place.
There are hundreds of smaller shipyards and marinas which service small commercial and private boats, in addition to large shipyards which service everything from small vessels and marine equipment to super structures.

Abrasive blasting at repair facilities presents an especially challenging task in terms of pollution control because this activity results in a very fine airborne dust which is difficult to contain, it is generated in large volumes, and it takes place near water resources. Add to this complexity, antifouling ingredients which can be deadly to water organisms. Abrasive blasting clearly is what is known as a "cross media" pollutant which affects air, water and land.

While there are a variety of pollutants that may result from activities at repair facilities: abrasive blast and paint, lubricants and oils, solvents, vessel discharge, storm water runoff, etc., all of which need to be properly managed to insure protection of the environment, this manual focuses on one of the biggest problems in the shipyard industry: controlling the pollutants associated with paint removal operations.

SECTION ONE

ABRASIVE BLASTING AND ANTIFOULING PAINT

There are a variety of abrasive blast materials that can be used in air or water blasting processes used to remove paint from vessels and marine structures. Blast material particles, also referred to as "grit", are about 1/8" in diameter. These normally jagged, or sharp-edged particles become rounded and somewhat reduced in size after being blasted against a vessel's hull, for example, to remove paint.

Vessels, depending on the size, can use an enormous amount of grit for both interior and exterior blasting. One large supertanker, for example, may require up to 40,000 tons of grit just to do interior blasting. The amount of grit needed to remove paint from a vessel's exterior depends on the surface condition of the hull (i.e., was the previous paint put on bare metal, or over existing paint), the nozzle diameter of the hose used in abrasive blasting, and the number of coats to be removed and other contract specifications.

Some of the brand names of abrasive blast material include: Black Blast, Black Beauty, Fines Blast and Green Diamond. The constituents of abrasive blast varies somewhat, but in general the primary components with approximate percentages are:

Silicon Dioxide	20-50%
Iron Oxide	15-40%
Aluminum Oxide	0-25%
Calcium Oxide	0-25%

These four components comprise up to 90 percent of the abrasive grit composition. Other abrasive grits may contain as much as 10-15 percent zinc oxide or 20-25 percent magnesium oxide. Trace elements in these abrasive grits include: potassium oxide, sodium oxide, copper, titanium and sulfur.

Spent abrasive blast material may contain a variety of pollutants. Fresh, or unused abrasive blast media is even considered a "dangerous" or "special" waste in some states due to gill abrasion which can be fatal to some fish; therefore, abrasive blast media, used or unused, should not be discharged into State waters.
When hydroblasting, rust inhibitors such as sodium nitrite or diamonium phosphate may be used. In certain situations, antifreeze may also be part of the water jet to reduce ice formations.

Antifouling paints are used on vessels and marine structures to control the growth and attachment of "fouling" organisms such as barnacles, seaweed and algae. This is the intended effect of antifouling ingredients in paint. However, some antifouling ingredients, such as Tributyltin (TBT) can have a deadly effect on species other than fouling organisms. TBT is highly toxic in small concentrations to fish, oysters, clams and other forms of water life, so proper management of TBT-containing paint, and while blasting vessels that have been painted with TBT paint, is extremely important.

How does Tributyltin, and other antifoulants get into the environment?

Here are some of the most common ways:

- External blasting out of dry docks or contained areas
- Uncovered or loosely covered sandblast waste piles where grit blows away, or rainwater leaches antifoulant into nearby surface water or groundwater
- Sweeping or hosing sandblast grit waste into water
- Submerging dry docks with grit waste on them
- Overspray of TBT or other antifouling paints

Not only can mismanagement of waste containing antifoulants kill water organisms, but mismanagement of antifouling paints is a violation of hazardous and solid waste regulations.

The following section provides suggested Best Pollution Prevention Practices that are intended to be used as general guidelines to achieve the underlying objective of protecting the air, water and land from abrasive blast media, which may or may not contain antifouling ingredients.

SECTION TWO

ABRASIVE BLASTING: BEST POLLUTION PREVENTION PRACTICES

It is easy to understand the magnitude of controlling the pollutants associated with paint removal operations when the multitude of marine paints, which contain hazardous and toxic chemicals, is considered. And this is just one aspect of the activities that go on in ship repair. Besides blasting operations which are ongoing, there is the potential for large quantities of paints, thinners and solvents to enter State waters, either by accidental spills, poor cleaning procedures or improper disposal. When these paints are blasted off of vessels and marine structures, thousands of tons of grit waste are generated. The following Best Pollution Prevention Practices describe various methods of containing abrasive blasting:

BPP ONE: SHROUDING

Vessel maintenance generally involves some amount of abrasive blasting with copper, nickel or some other type of slag, or steel shot. These operations may be carried out on the ship's interior tanks and compartments or on the exterior hull and upper decks. The use of blast abrasive or paint represents a major pollutant source which may be lost, directly or indirectly to the water during the repair work.

While performing abrasive blasting or painting operations in floating dry docks, wet slips and marine railways, or other areas where blast material may reach State water, shroud material should be erected to prevent the loss or scattering of these potential pollutants. Shroud material should be used in graving docks as well, particularly extending from the ship sides to the top of the graving dock walls. In addition, shrouding should be incorporated with all blasting or painting performed on super structures.

BPP OBJECTIVE:

The use of shrouds can reduce or prevent the loss of abrasive blast grit and paint to the water surface. Shrouding can also reduce the scattering effects of wind and localize the area needing cleanup.

CRITERIA:

The shroud must be large enough the adequately enclose or segregate the working area. The bottom of the shroud should be fastened to the dock floor.

The shroud must be sufficiently supported to withstand minor wind stress. Support structures should be used in conjunction with the shroud.

With the shrouding in place the drydock space beneath the shrouding would be considered a confined space. To comply with OSHA 1915 standards, fresh air respirators for all personnel is required and proper ventilation, blowers, fans and all electrical equipment must be intrinsically safe.

Floating Drydocks

It is recommended that lightweight, polyethylene shroud be used for vertical hanging. Small sections of the material can be tied together to form larger shrouds for hanging at the aft and bow sections of the dock. The shroud may have screened flaps or openings to lessen wind stresses. The material can also be manufactured with grommets and securing (spring type) hooks which are used to hang the shroud. Typically the shroud can be fastened to cables connected to dock wing walls or cables which are strung from the top of one wing wall to the other wing wall. Ropes or cables can be fastened to grommets on the center of the shrouds to enhance vertical hanging stability.

The material can also be used to shroud the larger sally ports of some docks. For work on upper sides of vessels, the shroud should be fastened from the ship decks to the dock wing walls. The bottom of the shroud should hang sufficiently upon the dock floor to allow it to be weighted down or fastened. Straw bales should be placed on the floor behind the bottom of the shroud. Periodically, scattered abrasive will be blown and trapped under the shroud. This material needs to be swept up daily to prevent it from escaping into the water. Shrouding, combined with other Best Pollution Prevention Practices should provide an effective method for controlling blast abrasive and paint overspray on floating dry docks.

Graving Docks

The primary concern at these facilities involves using shrouds to prevent blast abrasives and paint overspray from exiting the top of the dock. Therefore, shrouds should be erected between the vessel deck to the dock walls. Vessel deck abrasive blasting and painting activities should be shrouded in a dome-like fashion to prevent the scatter and loss of pollutants.

Marine Railways

Marine railways present a different problem in controlling spent abrasive blast material. These are areas that are essentially uncontained and open to the effects of the wind. Two methods are suggested to control abrasive scatter at railways. The first technique involves erecting poles or masts at each end of the railway in a semicircular fashion. The poles can hold rolled-up shrouds that are lowered when needed. Shroud is also hung vertically from the railway wing wall scaffold to prevent abrasive loss on the railway sides. The top is then protected by stringing shroud from the vessel deck to the side wall scaffolds. Some railways may not have side wall scaffolds, It is then necessary to erect masts which encircle the entire railway work area.

Another acceptable technique involves segregating the water surface from the railway work area. Masts are erected along the shoreline which hold the shrouds. The vessel is raised and the shrouds are strung to form a barrier between the water surface and the work area. A portable scaffold is then placed around the immediate work area of the vessel. The scaffold is covered with shroud material. The workman is required to work within the shroud scaffold, which must be moved as the workman moves along the length of the vessel. Abrasive material that escapes the shrouding scaffold will be further confined to the work area by the shoreline shrouding. Timely cleanup and railway underpaving play an important and equal role in ensuring that the pollutants will not enter State waters. A lighter may be required in conjunction with shrouding for ships that overhang a marine railway, or on the pier side of a vessel in a wet slip.

Wet Slip

Wet slips are the most difficult locations to attempt to control abrasive scatter and paint overspray. Such work in this area will most likely result in the loss of pollutants to the water surface. To properly conduct blasting and painting operations at wet slips, it will be necessary to use the pier, scaffolding, lighters and the vessel to erect shrouds. Only small sections of a vessel should generally be worked on at any time. Protecting surface waters from wet slip blasting and painting is a time consuming and difficult task which must conform to the varying size and shape of each vessel. This task can be made more efficient by erecting masts along the pier and by using magnets against the vessel hull to hold the shroud in place. The lighters and the pier should be cleaned up at the end of each work shift.

CONCERNS
To be effective, the shrouding must be properly designed, constructed positioned and erected.

The use of magnets to hold shrouding may be acceptable if sensitive electronic equipment is on board the vessel. Enhance lighting outline in OSHA 1915.92 standards and forced supply and exhaust ventilation may be required for the shrouded work areas.

While certain concentrations of blast dust are airborne and during all painting evolutions, the concentrations of fumes and dust will require continuous monitoring for the LEL and 02 contents by a Marine Chemist or OSHA Certified Competent Person.

BPP TWO: OVERWATER PROTECTION

General work and repairs are continually being performed around or adjacent to wet slip piers, floating dry docks, marine railways and the exterior and interior sides and the upper decks of ships. Much of this work generates trash and pollutants of various forms which potentially may fall onto the water surface below. The use and proper positioning of lighters (pontoons, small floating decks or barges, etc.) can enhance the ability to retrieve pollutants prior to inadvertent loss to surface waters.

BPP:
Provide and position a lighter adjacent to ships, floating dry docks, piers and marine railways. These work platforms provide a catch surface for trash, paint spray, grit, paint slop, oil slop, etc.

Lighters should be used to protect the water surface underneath and adjacent to vessels in wet slips and vessels which overhang marine railways and floating dry docks.

BPP OBJECTIVE:
The primary objective is to catch the waste pollutant material prior to being lost to the water surface where cleanup becomes more difficult. The lighters need not necessarily be used primarily for workmen or machinery support but rather to catch discarded materials and pollutants.

Lighters also provide a surface for performing work related operations. The lighter should carry a drip pan in which all fluids (paints, solvents, oils, etc.) are contained. A drop cloth should be placed under the drip pan to catch fluid "slosh" over the pan rim due to wave action or transport. Following use of the drip pan, it must be removed from the lighter and cleaned. The waste fluids should be placed in proper storage containers for subsequent disposal.

For abrasive blasting and painting operations, lighters are to be used in conjunction with shrouding. Booms and/or absorbent devices are to be placed around the lighter to contain contaminants which reach the water surface.

CRITERIA:
Proper positioning of the lighter is of utmost importance to prevent pollutants from reaching surface waters. The lighter must be large enough to catch falling pollutants and stable enough to support workmen and required equipment. A tarpaulin or other protective coverings should be employed if the spacing between flooring boards is great enough to allow pollutants to fall through. The mixing of paints, solvents, or other hazardous materials should not be permitted on the lighter. This should be performed at a designated mixing area.

CONCERNS:
Use of a lighter requires that cleanup operations are periodically performed. Cleanup of the lighter should occur daily, and if, possibly, after every work shift. Cleanup procedures include sweeping or vacuuming spent abrasive and trash and placing the debris into designated disposal containers.

BPP THREE: WATER BLASTING, HYDROBLASTING, WATER-CONE BLASTING AND SLURRY BLASTING

Water blasting, hydroblasting, water-cone blasting and slurry blasting is performed to either clean sediment and marine growth from vessel hulls or to remove the top layers of

hull paint. These techniques will generate large volumes of water with the potential of transporting existing pollutants to surface water.

BPP:
Water blasting, hydroblasting, slurry blasting and/or water-cone blasting should not be conducted unless prior cleanup of the dry dock or marine railway floor is complete.

Water blasting runoff should be channeled into floor sumps where the wastewater will be pumped to grit removal basins/sedimentation tanks for settling treatment. The effluent discharge from the sedimentation treatment must be NPDES permitted.

Prior to entering floor drains and sumps, water blasting runoff may also be channeled through straw bales and/or sand bags which will catch most of the particles of paint and marine growth. Once the floor is dry the collected particles may be removed employing graving dock and floating dry dock clean-up methods.

BPP OBJECTIVE:
Water blasting techniques produce a scattered water pattern which is difficult to control or immediately contain. Unless prior cleanup of the dock or marine railway floor has been conducted, it is difficult to prevent water blast from contacting pollutants.

CRITERIA:
Runoff generated from water blasting, hydroblasting, slurry blasting and/or water-cone blasting should not be allowed to discharge directly into surface waters from graving docks, floating dry docks, or marine railway work areas.

The design flow of the collection and treatment system must be adequate to receive the water blasting runoff flow rates. Special consideration should be given to pumping and treatment of slurry blast runoff.

CONCERNS:
All pump connections, valves, meters and couplings must be watertight. Leaks must be immediately repaired when discovered.

BPP FOUR: ABRASIVE BLAST MATERIAL CONTAINMENT

Abrasive blasting is generally one of the preliminary tasks performed when a vessel is docked for repairs and maintenance. The task typically involves blasting the vessel hull or upper decks with nickel, copper or some other type of slag or steel shot to remove layers of old paint. Blasting generates a tremendous volume of spent abrasive which must be cleaned up and contained on a frequent basis.

BPP:
Spent abrasive blast must be stored in proper containment vessels or structures while on the shipyard site. Containment bins, tanks or hoppers must have covers to prevent rainwater from entering the structure and percolating through the stored abrasive.

BPP OBJECTIVE:
The objective is to store all spent abrasive in appropriate containment vessels until ultimate disposal off site. Proper containment involves not allowing any stormwater runoff or accidental discharges to come into contact with the abrasive. This method eliminates the typical procedure of storing voluminous piles of spent abrasive on bare ground. Storing the abrasive in yard stockpiles promotes pollutant runoff.

CRITERIA:
The containment structures may consist of specifically designated hoppers for holding abrasive; metal bins with covers, or a concrete containment pit or slab (three-walled) with runoff channels to sedimentation treatment units.

CONCERNS:
Treatment units which provide a discharge must be NPDES permitted. The NPDES permit may require more advanced treatment than sedimentation.

There must be an appropriate storage volume available on site to contain all spent abrasive.

BPP FIVE: RECORD KEEPING

Due to the nature of the shipyard repair business, BPP installations are in constant need of repair, replacement, inspection and cleanup. Records indicating a history of maintenance should be kept to provide a good indication of the current reliability of existing BPP's.

BPP:
Records should be maintained to document BPP's at the facility. The type of records which should be maintained include, but are not limited to, the following:

1. Quantities of abrasive which are used for blasting and quantities which are retrieved through cleanup.

2. Date of installation of a BPP control, inspections and subsequent repairs or replacements to the BPP including such items as how often straw bales, absorbent booms and other filtering
devices are replaced and/or cleaned.

3. A listing of BPP equipment, and supplies.

4. Date, time, description and action taken for any chemical spills.

5. The location, quantities, destination and hauler of vessel discharge waters and spent abrasive material.

6. Waste inventory records.

CRITERIA:
Record keeping should be maintained by designated individuals responsible for the task. The records should be kept at a specified location for review upon request.

BPP SIX: BPP TRAINING

BPP:
Shipyard management should provide all employees with regularly scheduled Best Pollution Prevention Practices seminars and discussions related to shipyard pollutants and pollutant runoff. The training should emphasize procedure, BPP techniques and supervisory responsibility and accountability. Subcontracting firms in the shipyard should be strongly encouraged to participate in the BPP program.

BPP OBJECTIVE:
Training each employee about the fundamentals of BPP control lessens the chance of recurrent pollutant discharges. Providing each officer, manager, supervisor, dock master, etc., with a strong sense of BPP commitment ensures solutions for recurring problems.

CONCERNS:
The primary concern is that not enough emphasis is given to teaching employees about the rudimentary aspects of Best Pollution Prevention Practices. Each new employee should be made aware of the BPP's as part of new employee training.

1.0 INTRODUCTION

1.1 Environmental Technology Verification

The U.S. Environmental Protection Agency (EPA) through its Office of Research and Development (EPA-ORD) has instituted the Environmental Technology Verification (ETV) Program to verify the performance of innovative and improved technical solutions to problems that threaten human health or the environment. EPA created the ETV Program to substantially accelerate the entrance of new and improved environmental technologies into the domestic and international marketplaces. It is a voluntary, non-regulatory program. Its goal is to verify the environmental performance characteristics of commercial-ready technologies through the evaluation of objective and quality-assured data so that potential purchasers and permitters are provided with an independent and credible assessment of what they are buying and permitting.

The ETV Program does not conduct technology research or development. ETV test results are always publically available, and the applicants are strongly encouraged to ensure, prior to beginning an ETV test, that they are satisfied with the performance of their technologies. Within the ETV Program, this state of development is characterized as "commercial-ready ," and the ETV test is conducted on production units or prototypes having the major characteristics of commercial units.

The provision of high-quality performance data on fully-developed commercial technology encourages more rapid implementation of those technologies and consequent protection of the environment with better and less expensive approaches. The ETV Program is conducted by six ETV centers that span the breadth of environmental technologies.

1.2 Air Pollution Control Technology Verification Center

EPA's partner in the Air Pollution Control Technology Verification Center (APCTVC) is RTI, a non-profit contract research organization with headquarters in Research Triangle Park, NC. The APCTVC verifies the performance of commercial-ready technologies used to control air pollutant emissions. The emphasis of the APCTVC is currently on technologies for controlling particulate matter, volatile organic compounds, nitrogen oxides (NO_x), and hazardous air pollutants from both mobile and stationary sources. The activities of the APCTVC are conducted with the assistance of stakeholders from various interested parties. Overall APCTVC guidance is provided by the Stakeholders Advisory Committee (SAC), while the detailed development of individual technology ETV protocols is conducted with input from Technical Panels (TP) focused on each technology area.

The APCTVC develops generic verification protocols and specific test/quality assurance (test/QA) plans, conducts independent testing of technologies, and prepares ETV test reports and statements for broad dissemination. Testing costs are ultimately borne by the technology applicants, although initial tests within a given technology area may be partially supported with government funds.

US EPA ARCHIVE DOCUMENT

1.3 Mobile Sources Air Pollution Control Technologies

Control of emissions from mobile sources continues to be of great national importance. Several areas of the country are not able to attain ambient air quality standards. The mobile source provisions of the 1990 Clean Air Act Amendments (CAAA) are intended to reduce most vehicle-related air pollutants by more than 40 percent for 1996 and later model year vehicles and engines. Earlier engine models emit pollutants at higher levels, and as these engine are durable and have long useful lives, they will continue to emit pollutants at higher levels many years into the future. For these reasons, the EPA funded and the APCTVC SAC recommended inclusion of air pollution control technologies for mobile sources as a priority for ETV.

One important group of mobile source air pollution control initiatives is concerned with highway and nonroad use diesel engines. The diesel particulate standard for urban buses was reduced in 1993 by 60 percent, from 0.33 to 0.13 g/kWh (0.25 to 0.10 g/bhp-hr). The standard, which applies to urban transit buses, dropped to 0.094 g/kWh (0.070 g/bhp-hr) in 1994 and to 0.067 g/kWh (0.050 g/bhp-hr) in 1996. While existing engine technologies can meet these standards, future standards are expected to be increasingly stringent and will require the use of post-combustion emissions control technologies. New technologies are being developed to meet these goals. In addition, since a NO_x emission level below the level mandated allows the generation of credits through the Voluntary Diesel Retrofit Program (VDRP), pollution prevention becomes more cost effective, and innovations in less-polluting alternatives and control technologies are encouraged.

Retrofit mobile source control technologies are principally exhaust treatment emission control devices and engine modifications. Some require no mechanical changes to engines, while others will involve some modification of the engine or its control system.

Filters for particulate matter (PM) control and diesel exhaust catalysts (DECs) may make use of or require some integration with engines. Engine modifications, in the context of this protocol, refer to pollution reduction technologies integral to the engine or the engine control systems. All these technologies have the potential to affect engine performance, and the concurrence of the engine manufacturer that the changes are compatible with safe, efficient, and reliable operation in the engine is an important element in demonstrating commercial readiness and suitability for ETV. The technologies and their testing are discussed in more detail below.

Selective Catalytic Reduction (SCR) nitrogen oxides (NO_x) control technologies, fuels, fuel additives, reformulated fuels, and lubricants are specifically excluded from consideration under this protocol for testing as retrofit emissions control devices. Protocols for these technologies may be developed in the future.

1.4 The APCTVC Mobile Sources Verification Program

This generic verification protocol (GVP) provides the requirements for APCTVC's ETV of the performance of DEC, PM filter, and engine modification air pollution control technologies applied to highway and nonroad use diesel engines. Other technologies will be addressed

similarly. Other organizations [e.g., EPA's Office of Transportation and Air Quality (EPA-OTAQ) and the California Air Resources Board] also 'verify' the performance of mobile source emissions control devices under different protocols to meet the needs of those organizations. Specifically, EPA-OTAQ has established, for applicants who meet particular criteria, a generally parallel path that does not require the level of external QA that is required for APCTVC ETV. The technology applicant should discuss the intended application of the technology with the appropriate regulatory body to determine the most suitable path for "verification."

This GVP is intended to apply only to DECs, PM filters, and engine modifications and their combinations. The APCTVC reserves the right to evaluate each technology submitted for ETV and to determine the applicability of this protocol to that specific technology. Special testing may be required in some cases to maintain the integrity and credibility, and, therefore, the value of ETVs. The critical data quality objectives (DQOs) in this document were chosen to provide emissions measurements sufficient to support the VDRP and its emissions credit provisions. Emissions credit allowances will be set by the appropriate state regulatory authority or EPA-OTAQ. (As stated above, the VDRP approving agencies may have data requirements that are in addition to the ETV test report.)

This protocol was developed and has been reviewed by a technical panel composed of a broad group of stakeholders who have expertise in mobile source controls and come from the vendor, user, and regulatory spheres. Technical panel membership is dynamic, and its composition is expected to change over time as technical emphases change. The APCTVC will maintain membership balance on the panel.

The basic APCTVC ETV test will measure and report baseline emissions concentrations and rates for an engine prior to use of the retrofit technology and also the emissions concentrations and rates for this engine following retrofit. It will be conducted at an independent, third-party test laboratory. The data quality requirements of this generic protocol will be applied at approved test laboratories through the preparation of test-specific test/QA plans. Other laboratory-, application-, or technology-specific information may also need to be addressed in the test/QA plan, which is described in Section 10.0. In general, test/QA plans prepared by test laboratories will not be reviewed by the entire technical panel. However, because specific technology areas may require special expertise or emphasis, input and review will be obtained from an ad hoc subcommittee of the technical panel and/or outside experts when deemed appropriate by the APCTVC. Test results will be presented as ETV reports and statements.

1.5 Quality Management Documents

Management and testing in this APCTVC program are performed in accordance with procedures and protocols defined by the following:

1) EPA's ETV Quality and Management Plan (ETV QMP) (EPA, 1998a or the quality management plan current at the time of testing),
2) the APCT Quality Management Plan (QMP) (RTI, 1998),

US EPA ARCHIVE DOCUMENT

3) the Generic Verification Protocol for Diesel Exhaust Catalysts, Particulate Filters, and Engine Modification Control Technologies for Highway and Nonroad Use Diesel Engines (this document), and
4) the test/QA plan prepared for each specific test or group of tests.

EPA's ETV QMP lays out the definitions, procedures, processes, inter-organizational relationships, and outputs that will ensure the quality of both the data and the programmatic elements of the ETV Program. Part A of the ETV QMP contains the specifications and guidelines that are applicable to common or routine quality management functions and activities necessary to support the ETV Program. Part B of the ETV QMP contains the specifications and guidelines that apply to test-specific environmental activities involving the generation, collection, analysis, evaluation, and reporting of test data.

APCT's QMP describes the quality systems in place for the overall APCTVC. It was prepared by RTI and approved by EPA. Among other quality management items, it defines what must be covered in the GVPs and test/QA plans for technologies undergoing ETV testing.

Generic Verification Protocols (GVPs) are prepared to describe the general procedures to be used for testing a type of technology and define the critical data quality objectives (critical DQOs). The GVP for retrofit air pollution control technologies for highway and nonroad use diesel engines was written by the APCTVC with input from a technical panel and approved by EPA.

A test/QA plan is prepared for each test or group of tests. The test/QA plan describes, in detail, how the testing organization will implement and meet the requirements of the GVP. The test/QA plan also sets DQOs for any planned measurements that were not set in the GVP. The test/QA plan addresses issues such as the test organization's management structure, the test schedule, test procedures and documentation, analytical methods, record keeping requirements, and instrument calibration and traceability, and it specifies the QA and quality control (QC) requirements for obtaining ETV data of sufficient quantity and quality to satisfy the DQOs of the generic verification protocol. Section 10 of this GVP addresses requirements for the test/QA plan.

Because multiple testing organizations will be conducting the tests and the desirability to ensure comparability, the APCTVC will develop a prototype test/QA plan (not part of this GVP) for each type of technology. This prototype will be customized by the testing organization to meet its specific implementation of the Federal Test Procedures (FTPs) as defined in 40 CFR Parts 86 and 89, and the secondary measurements, subject to approval by the APCTVC and EPA-ORD. Testing arrangements that do not meet the requirements of the FTP will not be approved, and test instrumentation or test procedures that the APCTVC determines will compromise data reliability or comparability between testing organizations will not be approved.

US EPA ARCHIVE DOCUMENT

2.0 OBJECTIVE AND SCOPE

2.1 Objective

The objective of this GVP is to establish the parameters within which DECs, PM filters, and engine modification air pollution control technologies for highway and nonroad use diesel engines will be tested to verify their performance with uniform and consistent methodologies within the APCTVC. The protocol addresses the requirements for technology submission, outlines the test conditions and procedures to be used, and states the critical DQOs for ETV and states reporting requirements. The control technologies will be verified within a specified range of applicability, and ETV reports and statements will be produced for dissemination to the public.

2.2 Scope

APCTVC testing will be performed to quantify the effectiveness of commercially ready emissions control technologies that are intended for use on diesel engines considered mobile sources of air pollutants. Emissions testing under this ETV Program is based on the applicable FTPs for highway and nonroad engines. As performed by manufacturers to certify their engines, FTPs are fully defined by the regulations and consist of the engine-appropriate cold- and hot-start engine dynamometer tests conducted under specified load cycles. For purposes of this protocol, the number and type of FTP tests may be different from certification requirements, as determined by the applicant and the APCTVC to best verify the performance of the technology under consideration. However, the individual FTP test module -- the cold-start test or the hot-start test -- will be performed completely in accordance with the regulations. (The low NO_x and PM emissions from post-2001 engines are prompting development of new test procedures better suited to these emission levels. As these test procedures become standardized and acceptable to EPA, they will be acceptable for use in ETVs.) The pollutants of major interest are NO_x, hydrocarbons (HCs), PM, and carbon monoxide (CO). Other measurements will also be made of emissions (for instance, carbon dioxide[CO_2]) and operating parameters of the test engine and the control technology. Additional measurements may also be required if the technology might be reasonably expected to generate secondary emissions. Emissions will be measured along with other data useful for evaluating the performance of the technologies and the technologies' associated environmental and efficiency impacts. In this context, the effects of control technologies on fuel economy and engine performance and power will be of particular interest.

Also fundamental to this ETV protocol is providing emissions control efficiency information needed for applicants to participate in the EPA Voluntary Diesel Retrofit Program (VDRP). The VDRP is managed by EPA-OTAQ. The data quality objectives given in Section 2.3 were set to provide emissions control device performance data that can be used in submittals to the VDRP. VDRP determinations are made by EPA-OTAQ, which may require information not included in the ETV.

The APCTVC will consider applications for ETV of air pollution control technologies on test engines specified by the applicant. Depending on the expected application, the data collected,

US EPA ARCHIVE DOCUMENT

and the test design, the results obtained may be valid only for that single engine or to groupings of multiple engines. If application of single engine test results to an engine group is made by the regulatory body, the decision will be based on an expectation that the control device, if appropriately sized, will perform similarly on all the engines in that group. Generally, similar emissions control performance is expected from engines that have the same engine technology and use. The sensitivity of emissions control performance to engine type and usage is not known to be the same for all technologies, and the applicability decision will be made separately for each technology type and possibly for each technology. Previously obtained performance data may affect the decision. In all cases, the decision regarding applicability will be made by EPA-OTAQ, which should be contacted at the time a technology is submitted to obtain current information.

Implicit in the potential use of single engine ETV tests as predictive of performance over segments of the total engine population is the availability of non-proprietary application sizing information and that the technology be labeled. The purpose of this requirement is to allow the APCTVC and the potential technology user to evaluate the applicability of the verified technology to other applications. Applicants who utilize application sizing charts must verify their technologies on an engine at the most challenging end of the range of applicability. ETV reports and statements will report the results and the design guidance required to independently extend application of the technology to other engines in the same engine grouping.

To request ETV, the applicant applies to the APCTVC for the technology to be tested and proposes the test engine(s) to be used. The APCTVC will review the application and provide input as required to ensure that the engine(s) proposed are suitable and that the emission control equipment sizing is clear and correct. The equipment/technology will be applied to the engine(s) according to the applicant's instructions. ETV test results for the engine(s) will be reported in the ETV report and statement. The results will provide the emissions performance data required for the VDRP reviewing regulatory authority to determine the emission reduction capability of the technology.

2.2.1 Highway Engines

Applicants may choose to have their technologies verified on a single highway engine or multiple selected engines, depending on the applicant's intended use of the data. EPA-OTAQ will determine the extent of applicability of data from any given engine and should be consulted by the applicant for that purpose. Testing of emissions control technology intended to control emissions from highway diesel engines will be conducted generally under the provisions of 40 CFR, Part 86, Subpart N. The primary emissions measurements will be of NO_x, PM, HC, CO, and other FTP requirements. CO_2 and the engine operating parameters are required secondary measurements. Each engine in the test will be loaded by a dynamometer as described in the transient FTP. Each ETV test will consist of at least a single full FTP test (cold- and hot-start) and two additional hot-start tests (total of three hot-starts) on an emission-stabilized baseline engine and on the engine with the control technology in use. Additional hot-start tests may also be required to meet the number of test requirements described in Section 5, or the applicant may wish to run additional tests to narrow the confidence interval on the result. [An ETV

US EPA ARCHIVE DOCUMENT

requirement for multiple hot-start tests may be met using the hot-start results from full FTP test data (both cold- and hot-start), at the applicant's option.] Durability testing , which consists of ETV of aged control technology units as described in Section 5.2.9, is part of the ETV process. Emissions reductions will be computed relative to the baseline engine emissions.

2.2.2 Nonroad Engines

As with highway engines, applicants select the nonroad engines on which to test their technologies. The ETV testing of emissions from nonroad diesel engines will be conducted generally within the requirements of 40 CFR, Part 89, Subpart E. As for highway engines, the primary emissions measurements for nonroad engines will be of NO_x, PM, HC, CO, and other FTP requirements. CO_2 and engine operating parameters are required secondary measurements. The ETV testing will consist of three or more nonroad steady-state mode tests (40 CFR, Part 89, Subparts D and E), as described in Section 5. (Concerns about transient emissions from nonroad engines are prompting development of new test procedures. As these test procedures become standardized and are codified in the FTP, they will be included in the ETV test protocol.) The test must be conducted over all applicable modes of the test cycle appropriate to the engine (e.g., 8-mode test cycle for variable speed engines or 5-mode cycle for constant speed engines) or may be conducted over all modes at the applicant's request. The ETV report will reflect the extent of the test conducted. Each ETV test will consist of the same assemblage of FTP tests on the broken-in baseline engine and the engine with the control technology in use. Durability testing is required as described in Section 5.2.9. Composite emissions reductions are computed relative to the baseline engine emissions. In addition, the emissions results will be reported in composite and mode-by-mode to allow flexibility in use of the data for different engine applications.

2.2.3 Control Technologies

This GVP is specifically intended to include the following emissions control technologies:

1) DECs regenerated continuously or periodically,
2) PM filters, and
3) Engine modifications.

The basic ETV test remains the same for all emissions control technologies. However, the technologies interact differently with the various engines. Therefore, the engine grouping concept may be applied differently by EPA-OTAQ depending of the nature of the technology. In addition, where technologies require particular fuel characteristics or have other restrictions or interactions, applicants must specify these and any associated requirements in their ETV applications.

In all cases, the ETV test will be designed to reasonably isolate the effects of the retrofit technology from coincident engine adjustments and tune-ups. For example, a retrofit technology that required an engine tune-up following installation would be tested against a tuned-up baseline engine.

US EPA ARCHIVE DOCUMENT

Some technologies, by their nature, may reasonably require engine adjustments following installation. To be allowed, such adjustments must be part of the description of the technology, be included in the installation instructions, be described in the application, and be made by the laboratory technician and not by the applicant. They will be examined to determine the effect of those engine adjustments alone, and the baseline engine may be tuned to the same operating condition if the adjustments alone are considered to have a positive effect on emissions. This requires that the APCTVC and the testing laboratory be provided with a full disclosure of the working principles of the technology prior to developing the test. In these cases, the ETV report and statement will define the retrofit technology as consisting of both the device and the engine adjustments, with both required to achieve any emissions reduction observed.

2.2.4 Relationship of ETV Program to EPA-OTAQ VDRP Verified Technology List

EPA-OTAQ is charged with establishing a Verified Technology List of technologies capable of providing emissions reductions. The test results EPA-OTAQ will utilize to evaluate a technology may be generated following the ETV process, with the ETV report and verification statement serving as the data package to EPA-OTAQ. Other paths to the verified technology list also exist. The VDRP program is described and appropriate contacts are identified at http://www.epa.gov/otaq/retrofit/. The technology applicant should discuss the intended application of the technology with EPA-OTAQ to determine the most suitable evaluation path for the applicant's technology.

As of the date of this protocol, emissions test data from a full FTP test (whether highway or nonroad), that was generated by a manufacturer to obtain a certificate of conformity may be determined by EPA-OTAQ to constitute a valid data set for VDRP purposes. Certification data do not pass though the ETV Program. The certification and VDRP technology listing processes are independently performed by EPA-OTAQ. In addition, EPA-OTAQ has established for some applicants a technology evaluation pathway whose test requirements parallel those of this GVP, but with reduced QA requirements.

2.3 Data Quality Objectives (DQOs)

The data of primary interest in this ETV are the reduction in emissions of NO_x, HC, PM, and CO. (Numerous other measurements, including CO_2 emissions, will also be made as described in later sections. However, these are not considered critical, and the methods and data quality objectives will be stated in the test/QA plan for each technology.) The DQOs of this GVP are the requirements of the test methods specified in 40CFR Parts 86 or 89 for highway or nonroad diesel engines, respectively, when conducting the number and type of FTP tests called for by the approved test/QA plan for the technology. ETV tests that do not meet the FTP QA requirements must be repeated.

The number of and type of FTP tests (cold- and/or hot-start) required for ETV is determined from the following criteria:

US EPA ARCHIVE DOCUMENT

First, a minimum of three tests is required to provide the basic ETV result of a mean emission reduction and the 95% confidence interval on that mean based on measured variability for each of the measured emissions and test parameters. For highway engines this minimum is satisfied with one cold start test and three hot start tests. For nonroad engines three replicates of the appropriate test sequence (i.e., three 8-mode tests, or three 6-mode tests) are required. A three test minimum is currently the same as is required by the State of California for verification.

Second, additional tests may be required to meet the ETV requirement that the test/QA plan provide a 90% probability of detecting the expected emissions reductions when computed using the expected experimental errors for the various measurements. These criteria become controlling for low emissions reductions and/or high test variability. This is a planning requirement for the test/QA plan. The procedure to determine the appropriate number of tests is given in Section 5.

Third, additional tests may be desired by the applicant to reduce the width of the 95% confidence interval on the mean emission reduction. Section 5 provides additional explanation and example scenarios. This third criterion is a consequence of applying standard statistical procedures to the ETV test design and data analysis. At a fixed measurement variability, normal statistical procedures lead to a small number of tests giving a broader 95% confidence interval than a larger number of tests. To any regulator or potential technology user, an emission reduction of 40% ± 5% is better than 40% ± 20% and will be given more credence.

An applicant may conduct privately sponsored tests at a test laboratory for development purposes with the same test engine prior to and/or after conducting ETV tests. Such testing is understood to be common and important to ensure the technology is properly adjusted and tuned to the application. However, two important principles of ETV are that the verified technology be commercial ready when tested and that all data obtained under the ETV process be reported.

Therefore, preparation for the ETV test (submittal of the technology to the APCTVC, discussion of engine selection, and preparation of the test/QA plan) must be completed prior to conducting the ETV test itself. In particular, declaration of the test run which is to be the ETV test must be made prior to starting the test, the engine must be brought to a starting point in accordance with the test/QA plan, and the results of that test will be documented and reported in accordance with the test/QA plan. The data from all ETV tests will be retained and reported to the APCTVC, including invalid FTP test results. Data that meet the QA requirements of the FTP are considered valid and will be used to compute emissions reductions for ETV purposes. Section 8.0 addresses a technology applicant's options should the technology perform below expectations.

Tests conducted at qualified laboratories will be accepted as ETV tests provided the technology is submitted to the APCTVC and all requirements of this GVP are met, including approval of the test/QA plan prior to testing. This requires that the technology be submitted

US EPA ARCHIVE DOCUMENT

to the APCTVC, that a test/QA plan be prepared by the laboratory in conjunction with the APCTVC, and that the test/QA plan be approved by the APCTVC prior to testing. All QA requirements of the FTP methods must be met, and the test and test laboratory must meet the QA requirements of ETV as established in this GVP and the test/QA plan.

Engine emissions are expressed in grams of pollutant per kilowatt-hour (g/kWh) or in units of grams per brake horsepower-hour (g/bhp-hr). The primary measurement of HC and NO_x is normally concentration in the exhaust stream in parts per million by volume (ppmv), which is then converted to g/kWh in accordance with the FTP. For calculation of the technology's removal efficiency, the baseline emissions of the tested engine must also be known. The control technology performance will be reported as both absolute emissions in g/kWh and as percentage emissions reduction for a specific engine or engine family. The percentage emission reduction reported will be the mean emission reduction (relative to the baseline emission) with attendant upper and lower 95% confidence limits on that mean.

3.0 ETV TESTING RESPONSIBILITIES

This ETV program is conducted by the APCTVC under the sponsorship of the EPA-ORD and with the participation of technology applicants. The APCTVC is operated under a cooperative agreement by RTI, EPA's ETV partner. RTI's role as ETV partner is to provide technical and administrative leadership and either conduct or manage the conduct of ETV testing and reporting. Various subcontractors have roles in the APCTVC under RTI's management.

ETV tests are conducted by qualified test laboratories as contractors to RTI. Test laboratory-specific ETV test/QA plans are prepared by the testing laboratories to meet the requirements of the GVP.

The test/QA plan includes a chart that presents the test program organization and major lines of communication. The organizations involved in the ETV of mobile diesel engine air pollution control technologies are the EPA, RTI, testing laboratory, and technology applicant.

The primary responsibilities for each organization involved in the test program are:

1) The EPA-ORD, following its procedures for ETV, reviews and approves GVPs, test/QA plans, ETV reports and statements, and conducts QA audits.
2) The APCTVC prepares the GVP, provides oversight of the testing organization, provides a template for test/QA plans, and jointly with EPA-ORD reviews and approves the ETV reports and statements.
3) The testing organization prepares the test/QA plan in accordance with the GVP, coordinates test details and schedules with the applicants, conducts the tests, and prepares and revises draft ETV reports and statements. The testing organization QA staff is responsible for conducting internal QA on test results and reports.
4) EPA-ORD and/or APCTVC QA staff, at their discretion, will conduct assessments of the test organization's technical and quality systems.

US EPA ARCHIVE DOCUMENT

5) The technology applicant provides complete, commercial-ready equipment for ETV testing; provides logistical and technical support, as required; and assists the testing organization with operation and monitoring of the equipment during the ETV testing. The applicant's responsibilities are defined by a contract or letter of agreement with RTI..

4.0 TECHNOLOGY CAPABILITIES AND DESCRIPTION

This section outlines the information to be submitted by the ETV applicant, who is the basic source of the information regarding its mobile source air pollution control technology. This information is used by the test laboratory and APCTVC to prepare and review a test/QA plan that meets the requirements of the applicant and potential users of the ETV. No general outline can anticipate the data requirements for all possible technologies, so the applicant may be requested to supplement this outline when additional information is needed. This protocol has been developed with an awareness of the California Air Resources Board (CARB) "verification" program, and an application to CARB for retrofit "verification" is expected to provide adequate information. The basic application form to be used for ETV is that posted by EPA-OTAQ for the voluntary retrofit program, which can be found at:

http://www.epa.gov/otaq/retrofit/documents/forms.xls (as an Excel file)
http://www.epa.gov/otaq/retrofit/documents/forms.wk4 (as a Quattro file)

EPA-OTAQ has also posted application form guides, which can be found by replacing "forms" with "forms_guide" in the links above. The ETV test/QA plan will summarize this information in a form that clearly describes the technology being verified and states, for potential users of the technology, it's intended range of applicability as stated by the applicant. The test/QA plan will also include a draft ETV statement, based on Appendix A, customized to the specific technology being verified and measurements being made. The balance of this section independently describes the information requirements that led to development of these forms.

4.1 Basic Technology Identification and ETV Requirements

The basic technology identification should be a concise description of the technology that describes what is being verified and summarizes the emissions control performance expected. This information will be used to describe the technology in the ETV statement.

It should include such information as: technology name, model number, manufacturer's name and address, serial number or other unique identification, warning and caution statements, capacity or throughput rate, specific installation instructions, adjustments, limits on flow, temperature, pressure, and other information necessary to describe the specific technology and its intended use. Warranty information on the technology should be provided, including a sample warranty statement.

In addition, the applicant must state the goal of the ETV in terms of range of applicability

US EPA ARCHIVE DOCUMENT

(single or multiple engine, fuel requirements, equipment sizing, etc.), expected emissions reduction, and anticipated data use. This information will be used to develop the ETV test/QA plan.

4.2 Technology Descriptive Information

This section of the application is intended to describe the technology more fully. It will be used to prepare the test/QA plan and as a more complete description of the technology in the ETV report.

The applicant should describe the technology in a brief (300 word) statement, referring to the scientific principles of the technology's operation. Depending on the complexity of the technology, this may be followed by more extensive information. When applicable, the inclusion of schematic drawings explaining operation of the technology is encouraged. Examples of descriptive information that should be included are:

> Installation requirements. Space occupied, installation time, any physical modifications, placement issues, identification of ancillary equipment, if any, recommended duration of degreening as well as any special start-up procedures, and any other special requirements.
> Operation. Description to include identification of any favorable or unfavorable operating conditions and their effect on performance, fuel requirements (such as fuel sulfur limit), consequences of misfueling, identification of any chemicals or other consumable reactants, regeneration requirements, and expected engine back-pressure. Any requirement for energy sources (e.g., heat, electricity, compressed air, hydraulic fluid, pressure) external to the engine must be identified so they can be accounted for in the test/QA plan.
> Maintenance and warranty. Identification of recommended maintenance procedures, cleaning instructions, and spare parts and supplies. The warranty being offered should be stated.
> Operator or mechanic qualifications/training/safety. Qualifications needed to operate and service the technology, amount and type of training needed for operation and maintenance, and special safety considerations. Use of personal protective equipment (eyeglasses, hearing protection, etc.) should be noted.
> Secondary emissions. Identification of any secondary emission to the air that impacts water quality, or liquid or solid waste.
> Technology's life expectancy. Special attention should be given to the technology's regeneration requirements, if any, including a description of the regeneration process, any operating condition requirements for successful regeneration (e.g., temperature), and any manual or computer control of regeneration.

In the case of combinations of independent technologies that are being submitted for ETV, the description of the combined technology should completely identify and describe those technologies being combined and fully state the nature of the combined test and expected result.

US EPA ARCHIVE DOCUMENT

4.3 Technology Performance

The technology applicant must quantify the performance expected from the technology and support that expectation with background test data, including both initial performance and technology durability test descriptions and results. In general, these data will not be used to verify the performance of the technology, but will be used to develop an ETV test/QA plan that can adequately support the expected performance. The level of descriptive detail required for existing tests and their results cannot be generally stated because it is dependent on the ETV goals. Applicants are encouraged to supply pertinent data supporting their claims, which will include test facility descriptions, procedures, quality assurance and control, and any deviations from the FTP.

All aspects of the technology's performance should be addressed, beginning with performance during routine steady-state operation, but also including unsteady or unfavorable operation such as extended idling periods, uncontrolled regeneration, in-place maintenance, etc. Any known or expected impact the technology might have on the character of the emissions (gas composition, temperature, particle size or composition, etc.) should be identified.

4.4 Technology/Engine Interactions

The applicant must describe interactions between the proposed engine(s) and the technology, to include the known or expected effects of the technology on the engine(s). Backpressure, additional parasitic loads, fuel consumption, effects on engine durability, and oil consumption are of special concern. The relationship of the technology, engine control logic, and engine operation should be addressed for the engine(s) under consideration.

The applicant should defend the applicability of the technology to the applicable engine(s) by including exhaust temperature profiles, duty cycles, and other relevant performance information. The operating conditions that are favorable for the control technology should be compared with those of the engine.

The opinion of the engine(s)'s manufacturers regarding compatibility of the technology with their engine should be solicited, summarized, and the correspondence included in the application. Any known or anticipated impact of the technology on engine warranty is to be identified. The relationship between technology warranty and engine warranty should be discussed.

5.0 ETV TESTING

As stated in Section 2.3, Data Quality Objectives, an ETV test consists of a minimum of three FTP tests, and may include additional FTP tests to differentiate a low emission reduction technology from zero or to narrow the confidence limit on the mean emission reduction. Section 5.1 presents the methods that are used to design an ETV test to accomplish the applicant's goal, beginning from an expected emissions reduction for a

US EPA ARCHIVE DOCUMENT

particular pollutant and progressing through the methods used to generate the 95% confidence interval on the mean emission redutions. Section 5.2 presents other general ETV test considerations that apply to most retrofit air pollution control technologies. The remaining sections of this chapter are specific to the indicated types of technologies.

5.1 ETV Test Design

The data of primary interest in this ETV are the reduction in emissions of NO_x, HC, PM, and CO. (Numerous other measurements, including CO_2 emissions, will also be made as described in later sections. However, these are not considered critical, and the methods and data quality objectives will be stated in the test/QA plan for each technology.) NO_x emissions will be used to compute the number of tests required unless the applicant specifically requests that the reduction in another of the pollutants be used to control test design.

The number of and type of FTP tests required for ETV will be as follows:

A minimum of three tests is required to provide a mean emission reduction and the 95% confidence interval on that mean based on measured variability for each of the measured emissions and test parameters. For highway engines this minimum is satisfied with one cold start test and three hot start tests. For nonroad engines the minimum is satisfied with three replicates of the test sequence appropriate for the engine classification for which the technology is intended (i.e., three 8-mode tests for applicable engines, three 5-mode test for constant speed engines, three 6-mode test for variable speed engines under 19 kW.)

Additional tests may be required to meet the ETV requirement that the test/QA plan provide a 90% probability of detecting the expected emissions reductions when computed using the expected experimental errors for the various measurements. These criteria become controlling for low emissions reductions and/or high test variability for the controlling pollutant, which will be NO_x unless another pollutant is selected. This is a planning requirement for the test/QA plan. Section 5.1.1 describes the calculation procedure.

Relative to the minimum number, additional tests may be desired by the applicant to reduce the width of the 95% confidence interval on the mean emission reduction. Section 5.2 provides additional explanation and example scenarios.

5.1.1 Determination of Number of Tests Required to Meet ETV Requirements

Minimizing the cost of ETV testing is important, and reducing the number of tests conducted is one way to minimize cost. However, if too few tests are conducted, normal experimental variability could prevent the ETV from producing a useful outcome. For measurements having known variability and for stated expected reductions in emissions, the probability that a given number of tests can detect the expected reduction can be computed from statistical theory based on normal distributions. This ETV protocol requires that all ETV test/QA plans

US EPA ARCHIVE DOCUMENT

include sufficient tests to have a high probability of detecting the emissions reductions expected by the applicant. This requirement was implemented to ensure, as much as was practical, that the ETV test would accomplish the applicant's goals. This requirement will generally only be important to ETV test design for low emissions reductions and/or measurements having high variability. Specifically, the ETV test is to be designed such that there is 95% confidence that there is a 90% probability of detecting the emission reductions expected by the applicant, computed from the expected experimental variability for the various measurements. In this context, "detecting" means that the 95% confidence interval does not include zero emissions reduction. (This requirement is for test design purposes, and does not require that the test/QA plan be modified should actual test data show that the assumptions that went into the calculation were incorrect. However, as explained below, insufficient replication can result in inability to issue a verification and publication of an ETV report stating that a technology had no statistically significant benefit.)

An equation was derived to explicitly compute the number of tests required for normally distributed measurements having known standard deviations. Some results of applying that calculation are presented in Table 1 for PM and NO_x emission reductions. The equation used to compute the number of tests required is presented in Appendix B.

In Table 1 the baseline engine is assumed to be at a fixed emission value (the 1990 certification emission level for highway diesel engines) for PM (top of table) and NOx (bottom three rows). PM and NO_x measurements are used in Table 1 because the measurement standard deviations were known for one laboratory. The results in Table 1 are limited by the requirement in the derivation that the measurements be normally distributed with known variability. As will be shown in Section 5.1.2, the determination of the measurement variability from data, as will be done during the ETV data analysis, leads to a broadening of the confidence interval. Consequently, more tests than shown in Table 1 may be required under those conditions, and careful examination of the number of tests needed will be required during test/QA plan development.

The column headings in the first row of the PM and NO_x sections of the table give the assumption that installing the control technology gives emissions reductions of 5%, 20%, 50%, or 85% from the baseline emissions levels, which might be the applicant's estimate of emission reduction for different technologies. The second row gives the constant and known baseline engine (without control technology) variability when emitting at the 1990 certification level. The third row is the known measurement variability for the baseline engine after having been fitted with control technology that achieves the reduction shown in the column heading. (Variability is expressed as the known standard deviation at the emission level divided by the corresponding baseline engine mean emission and multiplied by 100%.) The variability increases as the emission reduction increases from left to right because the absolute error is roughly constant, while the magnitude is decreasing. The fourth row gives the calculated number of tests required to have 90% confidence that the 95% confidence interval about the mean expected emission reduction would not include zero.

US EPA ARCHIVE DOCUMENT

Table 1. Number of replicate tests (on both baseline and controlled engine) to achieve a 90% probability of detecting a PM emission reduction at a confidence level of 95%

Expected emission reduction (relative to the respective 1990 certification levels for PM and NO_x, respectively)	5%	20%	50%	85%
Variability for baseline engine PM measurement at 1990 levels	2%	2%	2%	2%
PM measurement variability at specified emission reduction	2%	2%	3%	10%
Number of tests required to have 90% probability (ETV requirement) of detecting expected PM emission reduction[a]	3	1	1	1
Variability for baseline engine NO_x measurement at 1990 levels	2%	2%	2%	2%
NO_x measurement variability at specified emission reduction	2%	2%	7%	NA[b]
Number of tests required to have 90% probability (ETV requirement) of detecting expected NOx emission reduction[a]	3	1	1	NA[b]

[a] Computed under the assumption of normally distributed measurements having known variability. Additional tests may be required for sample standard deviations obtained during ETV.

[b] NA = Not Available.

The fifth through the seventh rows (shaded) repeat the calculation for the NO_x measurement. No estimate of variability was available for the NO_x measurement at an 85% reduction from the 1990 level. Table 1 shows that, for both PM and NO_x, three tests are sufficient to distinguish between zero and emissions reductions as low as 5%, provided the estimates of measurement variability are met in the actual ETV. One test would be sufficient to detect the other emissions reductions, but three are required by ETV to provide a measured standard deviation. No specific estimates of variability for HC emissions were available, but at high emissions reductions (low absolute levels) the HC variability may be on the order of 30%. Three tests would not be sufficient in that case. In the development of the test/QA plan, the test laboratory will report its known measurement variability, and the expected number of tests required. This estimate will be reviewed by the APCTVC.

Appendix C presents a sensitivity analysis for additional levels of measurement variability. As explained in section 5.1.2, below, the number of tests may be increased further if an applicant desires to reduce the width of the confidence interval on the mean emission reduction.

5.1.2 Confidence Interval on the ETV Result

A consequence of the unavoidable variability in emissions measurements is that the mean of a small number of measurements has a small probability of giving the true emission reduction. In some cases it may not be possible to make a statistically-significant determination that the measured emission reduction is different from zero. The results of ETV measurements will be presented in verification statements and reports as the mean and

US EPA ARCHIVE DOCUMENT

95% confidence interval on that mean, calculated using the sample standard deviations determined from the ETV test data. Because sample standard deviations are available, the t-statistic is applied to compute the confidence intervals. This results in a broader error distribution than indicated in Table 1.

Table 2 illustrates the results that would be obtained for the PM emissions measurement variability numbers that were presented in Table 1 should those results be obtained during an ETV. Two additional 20% reduction columns have been added as examples of the effects of still higher variability at moderate reductions. (As was true in Table 1, the measurement variability in Table 2 is expressed as a measurement standard deviation divided by the baseline engine mean emission. However, relative to Table 1, the use of the t-distribution broadens the confidence interval.) The first three rows of Table 2 are the same as those in Table 1. Rows 5 through 7 give the two-sided 95% confidence intervals on the indicated mean percent emissions reduction from the 1990 certification emission value for three, six, and nine tests. For the 5% reduction column, Table 2 shows that the three test ETV minimum does not detect the 5% reduction in that a zero reduction is within the 95% confidence interval of -1.7 to 11.7% reduction. Six tests do detect the difference. Therefore, between three and six tests would be required.

The fourth and fifth columns of Table 2 illustrate the effects of higher variability levels for the controlled engine than were presented in Table 1 for a 20% emissions reduction, and more clearly show the potential benefits of additional testing. This hypothetical additional variability would arise from some interaction between the engine and the control device, because the variability of the test method is affected by modest changes in emissions levels such as are contemplated here. With 3 tests and an 8% test variability, the confidence interval on the mean reduction would be ± 16.4%. Obtaining the same mean from 6 tests, at the same variability, would give a confidence interval of ±6.9%, less than half the width of that with 3 tests.

Table 2. 95% confidence intervals on example mean emission reductions relative to baseline engine emissions at 1990 certification value.

Emission reduction, % of baseline engine emission	**5**	**20**	**20**	**20**	**50**	**85**
PM measurement variability for baseline engine, % of baseline engine emission	2	2	2	2	2	2
PM measurement variability for controlled engine, % of baseline engine emission	2	2	4	8	3	10
Number of replicate verification tests	**95% confidence intervals on emission reduction, % of baseline engine emission**					
3	5±6.7	20±5.6	20±8.9	20±16.4	50±4.5	85±3.8
6	5±2.8	20±2.4	20±3.8	20±6.9	50±1.9	85±1.6
9	5±2.1	20±1.7	20±2.8	20±5.1	50±1.4	85±1.2

US EPA ARCHIVE DOCUMENT

When planning a test, the ETV program will use the applicant's estimated emissions reduction, available test results, and experience with similar technologies to design an ETV that is capable of detecting the emission reduction expected and meeting the applicant's goals for confidence interval. However, the technology may not perform as expected. Section 8.0 addresses these circumstances.

5.2 General ETV Test Considerations

Unless specified otherwise, the general test considerations in this section will apply to all technologies covered by this protocol.

5.2.1 Submittal of Technologies and ETV Sequence

The ETV process begins with the applicant indicating to the APCTVC or to a test laboratory an interest in the ETV process. In either case, the second step is agreement between the APCTVC, the applicant, and the test laboratory regarding the general form of the ETV process and the responsibilities of all parties. This second step culminates with a formal application for ETV to the APCTVC, providing the information about the technology described in Section 4. The approximate cost of the ETV will be estimated and a contractual relationship between the APCTVC and the applicant will be started.

The test laboratory will then develop the ETV test/QA plan, reviewing it with the applicant and the APCTVC to ensure that it meets the requirements of the APCTVC, and, to the extent possible, accomplishes the applicant's goals for ETV. The test/QA plan will then be reviewed formally by the APCTVC and EPA. Test/QA plan development consists of a series of sequential activities, and the test/QA plan must be approved before testing begins.

The applicant will provide the technology to be tested. The applicant has the responsibility to arrange for provision of the engine on which the test will be conducted. Scheduling of the ETV test will be done by the test lab. De-greening of the technology is the applicant's responsibility, as is providing a de-greened unit and an aged unit for durability testing. The applicant must also provide any special ancillary equipment required for operation of the technology.

The applicant may choose to conduct private, proprietary test work at the test lab during the same time period the ETV is taking place. Such arrangements are between the test lab and the applicant. However, a clear differentiation is required between such private test work and the ETV test itself. In addition, the APCTVC must have adequate notice regarding an ETV test to be able to audit those tests if desired. The manner in which the start and end of the ETV test will be established and when the APCTVC will be notified must be specified in the test/QA plan. All ETV data must be reported.

US EPA ARCHIVE DOCUMENT

Following the ETV test, the test lab will report the data to the APCTVC, which will incorporate those data into the ETV report and statement. These documents will be reviewed with the test lab and the applicant to address comments and concerns as appropriate. The draft report will then be submitted to the multi-step EPA review and revised as needed. The ETV report and signed statement will be provided by the APCTVC to the applicant and EPA, and posted on the ETV and APCTVC websites.

5.2.2 Highway Engine ETV

Testing of technology intended to control emissions from highway diesel engines will be conducted generally under the provisions of 40 CFR Part 86 Subpart N. The primary emissions measurements will be of NOx, PM, HCs, CO, and other FTP specified emissions. CO_2 and other emissions and measurements described by this protocol are secondary measurements. Each ETV test will consist of the same number of tests on the baseline broken-in engine, the de-greened emission control technology, and the technology after aging. The number of tests will include a single cold- and hot-start highway transient FTP engine dynamometer test and may include additional hot-start tests in numbers determined using the test design procedure described above. The emissions reductions will be reported as the composite of the cold and mean of the hot starts, as required by the FTP, and as the mean and confidence interval on multiple hot-start tests. The smoke test is not required. The test parameters will be derived from the baseline engine mapping procedure. Emissions reductions will be computed relative to the baseline engine emissions using the same test cycle used during the baseline testing. As required by the FTP, tests that do not meet the FTP QA requirements must be repeated.

The test/QA plan for a specific technology will specify the engines that will be tested and any other aspects of the test that are specific to the technology or the test laboratory.

5.2.3 Highway Test Engines

The emissions characteristics of diesel engines of the same PM certification level are arguably similar because the engine technologies required to achieve those certification levels are likely to be similar. The emissions characteristics are also similar for engine families that have a breadth of technology similar to the tested engine. These similarities may provide an opportunity to group engines and reduce the ETV testing burden on applicants. As of the date of this protocol, EPA-OTAQ has proposed allowing the ETV test results from a single engine test to apply to multiple engines of different manufacturers. This is a decision that has been reserved by EPA-OTAQ, who should be consulted for details regarding the engines required to be tested as part of the ETV, the applicability of that ETV, and the magnitude of the associated emissions reduction credit under the VDRP.

US EPA ARCHIVE DOCUMENT

US EPA ARCHIVE DOCUMENT

5.2.4 ETV Testing of Nonroad Engines - General

The basic ETV test for nonroad engines will consist of the nonroad steady-state mode tests as described in 40 CFR, Part 89, Subpart E. The primary emissions measurements will be of NO_x, PM, HC, CO and other FTP required measurements. CO_2 emissions and other measurements described by this protocol are required secondary measurements. Each ETV test will consist of one or more full steady-state multimode FTP test(s) on the baseline broken-in engine, the de-greened technology, and the technology after aging. The test condition will be derived from the baseline engine mapping procedure. The test may be conducted over all modes of the Part 89 test or over portions selected by the applicant. The emissions reductions will be reported as the composite mean and confidence interval of the multiple test modes, computed as stated in the FTP.

Composite emissions reductions are computed relative to the composite baseline engine emissions and will be reported in composite and mode-by-mode to allow flexibility in use of the data for different engine applications.

5.2.5 Nonroad Test Engines

Following an approach similar to that used for the highway engines, the results of ETVs conducted on individual nonroad engines may be applicable to broader groups of engines. Technology applicants may select the engines on which to test their technologies. Coordination with EPA-OTAQ is encouraged because the decision regarding acceptable engine grouping has been reserved by EPA-OTAQ, who should be consulted regarding the engines required to be tested as part of the ETV, the applicability of that ETV, and the magnitude of the associated emissions reduction credit under the VDRP.

5.2.6 De-greening

For many hardware technologies, a brief period of use (de-greening) is needed to achieve a stable emissions reduction that allows representative testing. For instance, the pressure drop across a continuously regenerating PM filter reaches an equilibrium value. The de-greening time period required varies for different technologies, but is on the order of 25 to 125 hours. In all cases, the technology applicant must propose and justify the extent of the de-greening process in the ETV application. The APCTVC office will review and comment on this proposal, advise regarding the documentation requirements, and append the de-greening process description to the technology test/QA plan. When complete, the actual process used must be documented. A description of the de-greening process will be included in the ETV report.

For purposes of this protocol, the de-greening time requirement will be specified by the technology applicant as indicated by either previous testing or the requirements of the data user. To allow flexibility for the applicant, de-greening is not required to be conducted at the test lab. It may be done and documented by the applicant or conducted by the test lab by arrangement with the applicant. In either case, the applicant will ensure that such de-

greening activity documentation as start and stop date and time, engine and fuel description, and operating conditions are available and signed by the person responsible for the activity.

De-greening may occur in a laboratory or during in-use field operations on an engine that is equivalent to the proposed ETV test engine, or another engine of the same size which utilizes the same engine technology (and thus falls within the range of the technology's stated applicability).

5.2.7 Regeneration

Emissions control devices whose normal operation includes a periodic regeneration will be tested over sufficient test cycles (described below) until a test cycle includes a "regeneration" event. The verified emissions rate and emissions reduction achieved will be computed as the time-weighted average of the emissions rate and reduction achieved over this complete operating cycle.

Technologies that are continuously regenerated in normal operation are not the subject of this paragraph. Continuous cleaning PM filters should reach a stable operating range (as evidenced by near constant pressure drop) before testing, which may be accomplished in the de-greening activity.

5.2.8 Device Scaling

The performance of most retrofit air pollution control technologies is affected by the relative sizes of the tested technologies and the engines. Therefore, the use of single engine ETV tests as predictive of performance over segments of the total engine population requires the availability of non-proprietary application sizing information and that the technology be labeled. Sizing information may be provided in sizing charts [e.g., model AA1 is suitable for 37 to 74 kW (50 to 100 hp) engines, model AA2 to 74 to 112 kW (100 to 150 hp) engines] or through the release of basic design information (e.g., space velocity, catalyst loading). The purpose of this requirement is to allow the APCTVC and the potential technology user (the public) to evaluate the applicability of the verified technology to other applications. Applicants who utilize application sizing charts must verify their technologies on an engine at the most challenging end of the range of applicability. ETV reports and statements will report the results and the design guidance required to independently extend application of the technology to other engines in the same engine grouping. Device scaling and engine selection decisions will be explained and documented in the test/QA plan to the extent possible and will be reported in the ETV report. The ETV report and statement will report the results and the design guidance required to independently extend application of the technology to other engines in the same engine grouping.

5.2.9 Durability

The emissions reductions measured for the de-greened air pollution control device will not account for changes in product performance that may occur as the device ages. For

US EPA ARCHIVE DOCUMENT

participation in the VDRP, additional testing of an "aged" control device is required by EPA-OTAQ. If done as part of the ETV program, the "aged" device test will meet the same data requirements as a new device test. This testing is followed by extrapolation of the "initial de-greened" and "aged" verified performance measurement to the end of the warranted life of the control technology using a method determined by EPA-OTAQ. The aging process details and the extrapolation of the data to an "end of life point" are not part of this protocol. Provided for information only, the description below is current as of December, 2001 and may change. The details should be confirmed prior to ETV.

1) Aging entails subjecting the control device to operating conditions that cause normal wear equivalent to at least 33% of the Minimum Durability Testing Period established in the California "verification" procedure for diesel retrofit systems (CARB, 2001). Table 3 provides the testing periods that were current as of the date of this protocol. The applicant should verify the testing period current at the date of ETV. The technology applicants must conduct the aging process on their technology. They have discretion to tailor this process to product requirements. Applicants may age an exhaust catalyst by using it during real-world operation, or through accelerated bench testing. It is expected that applicants will submit identical parts (one in a de-greened state, one aged to at least 33% expected full-life) so that testing with the baseline may occur sequentially. However, applicants may conduct the de-greened and aged technology tests as separate tests, in which case the baseline engine test must be repeated. All aging protocols must accompany the ETV application and explain the technical basis for stating the aging protocol results in at least 33% full-life aging. If real-world aging is performed, the application must describe and provide documentation of the usage and maintenance history of the aged unit as well as the engine with which it was aged.
2) Emissions testing using the aged device will be part of the ETV process and will follow the same procedures applied to the de-greened technology. First, baseline emissions testing shall be conducted, followed by testing with the de-greened device, and then finally testing the aged device with a re-test of the baseline engine if technically feasible. An applicant may elect to age a unit to its full useful life prior to testing and request ETV on that basis.

3) The full useful-life reduction capabilities will be estimated by EPA-OTAQ following procedures they will provide to applicants.

5.2.10 Standard Diesel Test Fuel

The standard diesel test fuel for highway engines should meet the EPA specifications outlined in 40 CFR Part 86.1313-98 with the exception of the sulfur content. For nonroad engines, the test fuel

US EPA ARCHIVE DOCUMENT

Table 3. Minimum durability testing periods (CARB, 2001)

Engine Type	Engine Size	Minimum Durability Testing Period	
Highway	Light heavy-duty, generally 70 to 170 hp, GVWR[a] normally less than 19,500 lb.	5 yr or 60,000 miles (or equivalent time in hours)	
	Medium heavy-duty, generally 170 to 250 hp, GVWR[a] normally from 19,500 to 33,000 lb.	5 yr or 100,000 miles (or equivalent time in hours)	
	Heavy heavy-duty, generally exceeds 250 hp, GVWR[a] normally exceeds 33,000 lb.	5 yr or 150,000 miles (or equivalent time in hours)	
Nonroad and Stationary	Under 25 hp and for constant speed engines rated under 50 hp with rated speeds greater than or equal to 3,000 rpm	3 yr	1,600 hr operation
	At or above 25 hp and under 50 hp	4 yr	2,600 hr operation
	At or above 50 hp	5 yr	4,200 hr operation

[a]GVWR = Gross Vehicle Weight Rating

should be that described in 40 CFR Part 89.330 or another fuel as specified by the control technology applicant. Because the performance and durability of many types of diesel retrofit technologies are affected by the sulfur content of the diesel fuel, applicants should specify the maximum sulfur level of the fuel for which their technologies are designed. The sulfur content of the ETV test fuel should be no less than 66% of the stated maximum sulfur content. (Because refinery and blending operations are such that very low sulfur content control is difficult, test fuel with a sulfur content of 15 ppm or below is not constrained to the "66% rule". The actual sulfur content of the test fuel batch is to be reported.) Other test fuels should meet the applicable EPA specifications outlined in 40CFR Part 86.1313. Adding sulfur to the fuel by the test laboratories is permissible if necessary to achieve the required fuel sulfur content for either baseline or controlled engine tests.
During ETVs, baseline engines should be fueled with the standard fuels that are representative of nominal in-use fuels and controlled engines with low sulfur versions of the standard fuels that are representative of the applicant's recommended or required fuel.

5.2.11 Engine Performance and Power

Engine performance and power will be measured and reported for both the baseline engine (without the control device installed) and the engine with the control technology. Engine performance measurements will be made with the engine operating at maximum power (rated conditions) and at peak torque as defined in the applicable FTP.

US EPA ARCHIVE DOCUMENT

5.2.12 Fuel Consumption

Fuel consumption will be measured for both the baseline engine (without the control device installed) and the engine with the control device installed to determine the effect of the technology on fuel consumption. The engine fuel consumption measurements will be made at maximum power at rated conditions and at peak torque at intermediate speed. Multiple tests, if available, will be averaged. The results will be reported as a fractional increase or decrease relative to the baseline engine. Also reported will be fuel economy and brake specific fuel consumption from testing by the applicable FTP.

5.2.13 Back-pressure

Within the test cell, baseline engine back-pressure will be set to the value required by the applicable FTP (highway or nonroad). Once installed for the ETV test, the back-pressure of the retrofit control technology may be greater than the FTP requirement. If so, the ETV test will be conducted without adding additional back-pressure; if not, the test cell will be adjusted to meet the FTP requirements. Because back-pressure of a retrofit control technology may affect the performance of an engine, the ETV test will measure and report back-pressure with the control device at full-load and rated speed. Back-pressure will be measured and reported for both the baseline engine (as set for the FTP test without the technology installed) and the engine with the de-greened or aged control technology installed.

5.2.14 Control Technology Operating Temperature

Inlet (engine exhaust) and discharge temperatures must be measured for technologies that are either dependent on specific operating temperature ranges or affected by engine or exhaust temperatures.

5.2.15 Other Measurements and Conditions

ETV of technologies that may produce secondary pollutants or have other secondary effects must include measurement of those pollutants in the ETV test. CO_2 emissions, while not primary, must be measured using instrumentation and/or estimated from a carbon balance from the fuel usage. ETV must include the appropriate measurements for technologies that require other specific operating conditions or affect emissions over only a limited range of a particular pollutant. For example, because the long-term operation of DECs and PM filters is affected by the soluble organic fraction (SOF) of the PM, SOF must be measured during ETV testing for these and similar technologies. The details of these non-critical measurements and their QA goals will be part of the test/QA plan.

US EPA ARCHIVE DOCUMENT

5.3 ETV of DECs and PM Filters

5.3.1 Technology Description

For the purposes of this GVP, DECs are defined as devices made of active catalyst material (often containing precious metal) deposited on a support medium. The engine exhaust passes through the device, where the pollutants catalytically react and more environmentally acceptable reaction products are exhausted. PM filters mechanically trap PM emissions and subsequently oxidize them. Filters may also employ a catalyst for gaseous emissions control and to enhance the oxidation of the collected PM.

Physically, DECs and PM filters have the general appearance of a large muffler and are placed in the engine exhaust at approximately the same location. They are therefore well-suited to retrofit applications. No external liquid or gaseous reactants are required for them to function.

DECs have been reported to decrease HC and CO emissions by over 50%. They decrease PM emissions by about 20%. PM filters have been reported to decrease PM and HC emissions by 80% or more and to decrease CO at about the level achieved by exhaust catalysts. NOx emissions may be decreased slightly by exhaust catalysts.

Operational issues with DECs and PM filters are primarily achieving or maintaining adequate temperature within the device to complete the reactions and functioning satisfactorily with an accumulation of catalyst poisons and/or non-combustible lubricant ash residue. Lubricant ash and wear metals can largely be removed by infrequent “blowing” with compressed air. Guidance on technique and frequency of such cleaning should be provided in the ETV application.

5.3.2 Test Considerations Specific to DECs and PM Filters

The general considerations in Section 5.2 apply to DEC and PM filter ETV testing. ETVs of DECs and PM filters require measurement of the SOF content of the exhaust stream prior to entering the DEC. (The SOF may be measured for PM collected during the baseline engine test. The method to be used is the *Test Method for Soluble Organic Fraction (SOF) Extraction* [CARB, 1989] or a equivalent method recognized by EPA-OTAQ.) Both DECs and PM filters require measurements of inlet and outlet temperatures.

5.4 ETV of Engine Modifications

5.4.1 Technology Description for Engine Modifications

Engine modifications are defined as a change integral to an engine (e.g., component modifications or change or engine control system calibration change) that is proposed as an emissions reduction technology.

US EPA ARCHIVE DOCUMENT

5.4.2 Test Considerations Specific to Engine Modifications

The general considerations in Section 5.2 apply to engine modification ETV. Baseline engine performance will be measured prior to modification, followed by modification of the baseline engine in accordance with the application instructions, operation for a de-greening/stabilization period, and then measurement of the de-greened technology's performance. An aged engine modification technology's emissions performance will be evaluated as described in Section 5.2.9. However, there is no requirement to re-run the baseline engine which was modified. It cannot be shown that a modified engine can be returned to its original state to again serve as a baseline.

Engine modifications whose use is warranted by engine manufacturers will be taken to have no adverse impact on engine durability, and that endorsement will be noted in the verification report (VR) and verification statement (VS) along with the verified emissions reductions for the aged engine. The lack of any verified knowledge regarding the impact on engine durability of technologies not warranted by the engine manufacturer will similarly be noted.

6.0 REPORTING AND DOCUMENTATION

This section describes the procedures for reporting data in the VR and VS. The specifics of what data must be included and the format in which the data must be included are addressed in this section (e.g., QA/QC summary forms, raw data collected, photographs/slides/video tapes). The VR for each technology will include near it's beginning the VS. The VS is a short summary of the ETV results. An example draft is attached as Appendix A. The VR, including the VS, will be written by the APCTVC based on the test report submitted by the testing organization. The VR and VS will be reviewed by the APCTVC and the technology applicant before being submitted to EPA for review and approval as specified in the ETV QMP.

6.1 Reports

Based on the test report from the laboratory, the APCTVC will prepare the draft VR, which includes the following topics:

1) VS;
2) Introduction;
3) Description and identification of product tested;
4) Procedures and methods used in testing;
5) Statement of operating range over which the test was conducted;
6) Summary and discussion of results as required to:
    a) Support the VS,
    b) Explain and document necessary deviations from test plan, and
    c) Discuss QA issues;
7) Conclusions and recommendations;
8) References; and

US EPA ARCHIVE DOCUMENT

9) Appendices:
   a) QA/QC activities and results,
   b) Raw test data, and
   c) Equipment calibration results.

The VS will include the following:

10) Technology applicant's name and technology's descriptive information,
11) Summary of ETV test program,
12) Results of the ETV test,
13) Any limitations of the ETV results, and
14) Brief QA statement.

Review and approval of the draft ETV report and statement are as described in Section 3.0. A draft VS is attached to this protocol as Appendix A.

6.2 Data Reduction

Data from measurements made as part of the ETV test will be reported as emissions rates in g/kWh (g/bhp-hr) and as percentage emission reductions from the baseline engine. The confidence limits will be presented as well as the mean emissions reduction, as discussed in Section 5.1.2. When they would be helpful to the mobile sources community because of established usage, the appropriate English Engineering units will be supplied parenthetically.

7.0 DISSEMINATION OF ETV REPORTS AND STATEMENTS

After a retrofit control technology has been tested and the draft VR and VS received from the testing organization, the APCTVC will send a draft of both to the applicant for review prior to submission to EPA-ORD and release of the approved report to the public. This gives the applicant opportunity to review the results, test methodology, and report terminology while the drafts remain working documents and are not publically accessible. The applicant may submit comments and revisions on the draft statement and report to the APCTVC. The APCTVC will consider these comments and may suggest revisions of its own.

After incorporating appropriate revisions, the draft final VR and VS will be submitted to EPA-ORD for review and approval. A signed original VS and VR will be filed and retained by the APCTVC, and signed originals will also be provided to the applicant and to EPA. Three additional paper copies of the ETV report will be provided to the applicant. Further distribution of the ETV report, if desired, is at the applicant's discretion and responsibility. However, approved VSs and VRs will be posted on the ETV web site for public access without restriction. The VR report appendices will not be posted on the website, but will be publically available from the APCTVC.

US EPA ARCHIVE DOCUMENT

8.0 APPLICANT'S OPTIONS SHOULD A TECHNOLOGY PERFORM BELOW EXPECTATIONS

ETV is not a technology research and development program; technologies submitted for ETV are to be commercial-ready and with well-understood performance. Tests that meet the ETV data quality requirements (a valid FTP test) are considered valid and suitable for publishing. However, a technology may fail to meet the applicant's expectations. Based on limited testing, for instance, the applicant might expect an emission reduction of 30% ± 7% result. However, the actual ETV result from the more complex FTP test cycle might be 20% ± 15%. The APCTVC will use its experience to avoid this situation, but it is possible. In this case, the applicant may choose to schedule additional tests, may accept the result and complete the verification, or may request that a VS not be issued. However, ETV reports are always in the public domain. VRs will be written and will be available from EPA-ORD for review by the public regardless of a request not to issue a verification statement, and summaries of the results of ETV testing may be published by ETV and/or EPA-OTAQ.

Another example of a technology not meeting expectations would be an expected result of a mean of 10% reduction with a confidence interval of ± 5% reduction, but an actual ETV mean reduction of 5% with a confidence interval of ± 7% reduction. In this case, the data are insufficient for ETV to verify that the technology does anything at all. Additional tests must be scheduled and a statistically significant reduction obtained for a VS to be issued. Inability to detect a statistically significant emission reduction (equivalently, failure to have sufficient tests) will prevent completion of the ETV, and the results of the ETV will be reported publically stating that performance could not be distinguished from 0% reduction. An ETV statement will not be issued in these cases.

In either of these cases, the applicant may improve the product and resubmit it under a new model identification for ETV testing. ETV Statements for acceptable tests of the new product will be issued as they are processed by the APCTVC and EPA-ORD (except that the results for several identical tests performed in rapid succession will all be released at the same time).

9.0 LIMITATIONS ON TESTING AND REPORTING

To avoid having multiple ETV reports for the same product and to maintain the ETV testing as a cooperative effort with the applicant, the following restrictions apply to ETV testing under this protocol:

1) Applicants may submit only products they manufacture or whose distribution they control. Applicants may not submit for ETV testing control devices whose use is not in their control except with the agreement of the manufacturer or vendor.
2) For a given product (e.g., brand and model), APCTVC policy is that only one ETV report and statement will be issued for any single application.
3) Air pollution control technology frequently performs differently in different

US EPA ARCHIVE DOCUMENT

applications. Applicants may request additional tests of essentially identical technology if it is being applied to pollution sources that are clearly different from those for which ETVs have been obtained.

10.0 REQUIREMENTS FOR TEST/QA PLAN

10.1 Quality Management

All testing organizations participating in this ETV Program must meet the QA/QC requirements defined below and have an adequate quality system to manage the quality of work performed. Documentation and records management must be performed according to the *ETV Quality and Management Plan for the Pilot Period (1995-2000)* (ETV QMP, EPA, 1998a). Testing organizations must also perform assessments and allow audits by the APCTVC (headed by the APCT QA Officer) and EPA corresponding to those in Section 11.

All testing organizations participating in the Retrofit Air Pollution Control Technologies for Highway and Nonroad Use Diesel Engines Program must have an ISO 9000-accredited (ISO, 1994) or ANSI E4-compliant (ANSI, 1994) quality system and an EPA- or APCTVC-approved QMP.

10.2 Quality Assurance (QA)

All ETV testing will be done following an approved test/QA plan that meets *EPA Requirements for Quality Assurance Project Plans* (EPA, 2001a) and Part B, Section 2.2.2 of EPA's ETV QMP (EPA, 1998a). These documents establish the requirements for test/QA plans and the common guidance document, *Guidance for Quality Assurance Project Plans* (EPA, 1998b), provides guidance on how to meet these requirements. The APCT Quality Management Plan (RTI, 1998) implements this guidance for the APCTVC.

ETVs conducted under this generic protocol utilize test procedures described in the FTP (40 CFR Part 86 for highway engines and 40 CFR Part 89 for nonroad engines). The test/QA plan must describe, in adequate detail, how the FTP test methods are implemented by the testing organization. Replication of the FTP text is neither expected nor desired. The test/QA plan should reference the FTP in detail, by section and subsection, as appropriate for the topic under consideration. Any deviations from the FTP must be identified and explained. Internal standard operating procedures (SOPs) may be referenced provided they are available for audit review. (SOPs need not be incorporated into the test/QA plan except by reference. If considered proprietary to the test organization, they should be clearly marked.) When the FTP offers alternative test procedures or equipment, the test/QA plan must identify the alternative implemented. Similarly, if a range of operating parameters is allowed by the FTP, the specifics of the particular implementation must be provided. For a test organization with multiple test cells, these details may be tabulated and incorporated by attaching a table and identifying the test cell on the test report. Steps the testing organization will take to ensure acceptable data quality in the test results are also identified in the test/QA plan. As above, detailed reference to SOPs, the calibration portions of the FTP, or other

US EPA ARCHIVE DOCUMENT

available documents is encouraged. Any needed SOPs will be developed in accordance with *Guidance for Preparing Standard Operating Procedures (SOPs)* (EPA, 2001b.)

The testing organization must prepare a test/QA plan and submit it for approval by the APCTVC. The test/QA plan must be approved before the test organization can begin ETV testing.

A test/QA plan contains the elements listed below, the contents of which may be stand alone or include references to the FTP or other widely distributed and publically available sources. Legible hand-notated diagrams from the FTP are acceptable. If specific elements are not included, an explanation for not including them must be provided.

1) Title and approval sheet;
2) Table of contents, distribution list;
3) Test description and test objectives;
4) Identification of the critical measurements, data quality objectives (DQOs) and indicators, test schedule, and milestones;
5) Organization of test team and responsibilities of members of that team;
6) Documentation and records;
7) Test design;
8) Sampling procedures;
9) Sample handling and custody;
10) Analytical procedures;
11) Test-specific procedures for assessing data quality indicators;
12) Calibrations and frequency;
13) Data acquisition and data management procedures;
14) Internal systems and performance audits;
15) Corrective action procedures;
16) Assessment reports to EPA;
17) Data reduction, data review, data validation, and data reporting procedures;
18) Reporting of data quality indicators for critical measurements;
19) Limitations of the data; and
20) Any deviations from methods from this generic verification protocol.

The APCTVC will provide a test/QA plan template that illustrates it's expectations.

10.3 Additional Requirements to be Included in the Test/QA Plan

The test/QA plan must include or reference a diagram and description of the extractive gaseous measurement system to be used for the testing and a list of the reference analyzers and measurement ranges to be used for quantifying the concentrations of all gaseous compounds to be measured, including both primary and ancillary pollutants.

The test/QA plan must include or reference a schematic drawing showing all sample and test locations, including the inlet and outlet to the technology sampling locations. The location of

Item E 000063

US EPA ARCHIVE DOCUMENT

flow disturbances and the upstream and downstream distances from the sampling ports to those flow disturbances must be noted. The number of traverse points that will be sampled must be provided.

The test/QA plan must include or reference the appropriately detailed descriptions of all measuring devices that will be used during the test.

The test/QA plan must explain or reference the specific techniques to be used for monitoring process conditions appropriately for the source being tested. It must also note the techniques that will be used to estimate any other operational parameters.

The test/QA plan must include and document estimates of historical measurement variability that will be used, as discussed in Section 5.1.1, to compute the number of tests required and provide confidence intervals on single test ETVs.

11.0 ASSESSMENT AND RESPONSE

Each independent test laboratory must conduct internal assessments of its quality and technical systems and must allow external assessments of these systems by the APCTVC QA personnel and by EPA QA personnel. After an assessment, the test laboratory will be responsible for developing and implementing corrective actions in response to the assessment's findings.

As appropriate, the APCTVC and/or EPA will conduct assessments to determine the testing organization's compliance with its test/QA plan. The requirement to conduct assessments is specified in EPA's *Quality and Management Plan for the Pilot Period (1995 - 2000)* (EPA, 1998a), and in RTI's QMP (RTI, 1998). EPA will assess RTI's compliance with RTI's test/QA plans. RTI will assess the compliance of other organizations with their test/QA plans. The assessments will be conducted according to *Guidance on Technical Audits and Related Assessments for Environmental Data Operations* (EPA, 2000) and *Guidance on Assessing Quality Systems* (EPA, 2001.)

11.1 Assessment Types

Quality system assessment - Qualitative assessment of a particular quality system to establish whether the prevailing quality management structure, policies, practices, and procedures meet EPA requirements and are adequate for ensuring that the type and quality of measurements needed are obtained.

Technical systems audit - Qualitative on-site audit of the physical setup of the test. The auditors determine the compliance of testing personnel with the test/QA plan.

Performance evaluation audit - Quantitative audit in which measurement data are independently obtained and compared with routinely obtained data to evaluate the accuracy (bias and precision) of a measurement system.

US EPA ARCHIVE DOCUMENT

Audit of data quality - Qualitative and quantitative audit in which data and data handling are reviewed and data quality and data usability are assessed.

Surveillance audit - Observation of ongoing work to document conformance with specified requirements and/or procedures, such as those given in a test/QA plan or SOP.

11.2 Assessment Frequency

Activities performed during ETV performance operations that affect the quality of the data shall be assessed regularly and the findings reported to management to ensure that the requirements stated in the generic verification protocols and the test/QA plans are being implemented as prescribed.

The types and minimum frequency of assessments for the ETV Program are listed in Part A Section 9.0 of EPA's *Quality and Management Plan for the Pilot Period (1995 - 2000).* Tests conducted by the APCTVC will have at a minimum the following types and numbers of assessments:

1) Technical systems audits and surveillance audits: Self-assessments (qualitative) by test laboratory as provided for in the test/QA plans and at least one independent assessment of the test laboratory.
2) Performance evaluation audits: Self-assessments (quantitative) by test laboratory as provided for in the test/QA plans and at least one independent assessment of the test laboratory.
3) Audits of data quality: Self-assessments (quantitative and qualitative) by the test laboratory of at least 10% of all the ETV data with detailed reports of the audit results to be included in the data packages sent to the APCTVC for review.
4) Assessements of quality systems: Self-assessments by the test laboratory as provided for in the test/QA plans and at least one independent assessment of the test laboratory.

The independent assessments of tests conducted by RTI will be performed by EPA. The independent assessments of other organizations will be by RTI.

11.3 Response to Assessment

When needed, appropriate corrective actions shall be taken and their adequacy verified and documented in response to the findings of the assessments. Data found to have been taken from non-conforming technology shall be evaluated to determine its impact on the quality of the required data. The impact and the action taken shall be documented. Assessments are conducted according to procedures contained in the APCT QMP. Findings are provided in audit reports. Responses by the test laboratory to adverse findings are required within 10 working days of receiving the audit report. Follow up by the auditors and documentation of responses are required.

US EPA ARCHIVE DOCUMENT

12.0 SAFETY MEASURES

12.1 Safety Responsibilities

The test laboratory's project leader is responsible for ensuring compliance with all applicable occupational health and safety requirements. Each individual staff member is expected to follow the requirements and identify personnel who deviate from them and report such action to their supervisor.

12.2 Safety Program

The test company must maintain a comprehensive safety program and ensure that all test personnel are familiar with and follow it.

APPENDIX A: EXAMPLE VERIFICATION STATEMENT

Appendix A is an example verification statement written for a generic PM filter control technology. The technology is assumed to be directed at a highway use engine. It is assumed to be an efficient control device, requiring only a single test by the minimum-number-of-tests calculation. The PM values in Table A-2 are taken from the 85% reduction column of Table 3, while the other values are completely hypothetical.

This generic verification statement is intended only to show the form of a verification statement. It will require modification for each technology verified, depending on the details of that technology's design, construction, and operation. The test/QA plan written for each test will include a draft verification statement customized for the technology actually being tested. The text of that specific verification statement will address the significant parameters that apply to the technology tested.

The U.S. Environmental Protection Agency (EPA) has created the Environmental Technology Verification (ETV) Program to facilitate the deployment of innovative or improved environmental technologies through performance verification and dissemination of information. The goal of the ETV Program is to further environmental protection by substantially accelerating the acceptance and use of improved and cost-effective technologies. ETV seeks to achieve this goal by providing high quality, peer reviewed data on technology performance to those involved in the design, distribution, financing, permitting, purchase, and use of environmental technologies.

ETV works in partnership with recognized standards and testing organizations; stakeholder groups which consist of buyers, vendor organizations, permitters, and other interested parties; and with the full participation of individual technology developers. The program evaluates the performance of innovative technologies by developing test plans that are responsive to the needs of stakeholders, conducting field or laboratory tests (as appropriate), collecting and analyzing data, and preparing peer-reviewed reports. All evaluations are conducted in accordance with rigorous quality assurance protocols to ensure that data of known and adequate quality are generated and that the results are defensible.

The Air Pollution Control Technology Verification Center (APCTVC), one of six centers under the ETV Program, is operated by the RTI, in cooperation with EPA's National Risk Management Research Laboratory. The APCTVC has evaluated the performance of a *TYPE* emission control technology for mobile diesel engines, the *TECHNOLOGY* by *COMPANY NAME*.

Item E 000069

US EPA ARCHIVE DOCUMENT

ETV TEST DESCRIPTION

All tests were performed in accordance with the APCTVC *Generic Verification Protocol for Diesel Exhaust Catalysts, PM Filters, and Engine Modification Technologies for Highway and Nonroad Use Diesel Engines* and the specific technology test plan "ETV Test/QA Plan for *TECHNOLOGY NAME*" These documents include requirements for quality management, quality assurance, procedures for product selection, auditing of the test laboratories, and test reporting format.

The mobile diesel engine air pollution control technology was tested at *TEST LABORATORY*. The performance verified was the percentage emission reduction achieved by the technology for particulate matter (PM), nitrogen oxides (NO_x), hydrocarbons (HCs), and carbon monoxide (CO) relative to the performance of the same baseline engine without the technology in place. Operating conditions were documented and ancillary performance measurements were also made. The basic modules of the test procedure are found in the federal test procedures (FTPs) for highway engines (40CFR, Part 86, Subpart N) and nonroad engines (40CFR, Part 89, Subpart E). For highway use, a single full FTP test was conducted, augmented by additional hot start transient tests as needed to meet the requirements of the generic verification protocol (GVP). For nonroad use, one or more multimode tests were conducted as described in the GVP. A summary description of the ETV test is provided in Table A-1.

Table A-1. Summary of the conditions for ETV test of *TECHNOLOGY NAME* on ENGINE DESCRIPTION.

Test Conducted	Highway Transient FTP
Engine Family	*ENGINE MFGR NAME* Series *XXXYYY*, ??? operating hours prior to test
Engine Size	YYY kW (XXX hp)
Technology	ACME Mark II PM Trap, Model AA1 for diesel engines up to 150 hp on standard fuel
Technology description	Honeycomb PM filter packaged in an muffler-sized can for retrofit installation by a moderately skilled mechanic. No engine modifications required.
Test cycle or mode description	1 full FTP test (1 cold start and 1 hot start)
Test fuel description	EPA standard diesel per 40 CFR Part 86.1313-98
Critical measurements	PM, NOx, HCs, and CO per the FTP
Ancillary measurements	CO_2, backpressure at engine exhaust port, exhaust temperature, fuel consumption, regeneration requirements

VERIFIED TECHNOLOGY DESCRIPTION

This verification statement is applicable to the *TECHNOLOGY NAME* (to include model number and other identifying information as needed), which is an cordierite-based PM filter manufactured by *MANUFACTURER NAME*. *TECHNOLOGY NAME* is packaged and marketed for particular engine families (for example, Model AA1 is properly sized for the A1A1 engine) or as a unit suitable for use on engines below a particular diesel power rating. The unit whose performance was verified was the Model AA1, which is rated for engines up to YYY kW (XXX hp) fueled by standard diesel fuel.

This verification statement describes the performance of *TECHNOLOGY NAME* on the diesel engine

US EPA ARCHIVE DOCUMENT

identified in Table A-1. The retrofit device, *TECHNOLOGY NAME*, is expected to provide similar emissions control performance on other engines having similar exhaust stream characteristics (similar fuel and engine technology) when properly sized for the application.

VERIFICATION OF PERFORMANCE

TECHNOLOGY NAME achieved the emissions reduction shown in Table A-2 at the stated conditions. The number of required ETV tests was estimated to be one complete FTP test, and this

estimate was confirmed by the ETV test results. Table A-2 may include ETV results for both the initial operation (degreened) and for the technology following the stated period of aging. For the

US EPA ARCHIVE DOCUMENT

purposes of determining the status of the technology in regard to EPA's voluntary retrofit program, the prospective user is encouraged to contact EPA-Office of Transportation and Air Quality (OTAQ) or visit the retrofit program web site at http://www.epa.gov/otaq/retrofit/.

The APCT QA Officer has reviewed the test results and quality control data and has concluded that the data quality objectives given in the generic verification protocol and test/QA plan have been attained.

During the ETV tests, EPA or APCTVC quality assurance staff conducted technical assessments at the test laboratory. These confirm that the ETV tests were conducted in accordance with the test laboratory's EPA-approved test/QA plan.

This verification statement verifies the emissions characteristics of *TECHNOLOGY NAME* within the stated range of application. Extrapolation outside that range should be done with caution and an understanding of the scientific principles that control the performance of *TECHNOLOGY NAME*. This verification focused on emissions. Potential technology users may obtain other types of performance information from the manufacturer.

In accordance with the generic verification protocol, this verification statement is valid commencing on *DATE* indefinitely for application of *TECHNOLOGY NAME* within the range of applicability of the statement.

NOTICE: ETV verifications are based on an evaluation of technology performance under specific, predetermined criteria and the appropriate quality assurance procedures. EPA and RTI make no expressed or implied warranties as to the performance of the technology and do not certify that a technology will always operate as verified. The end user is solely responsible for complying with any and all applicable federal, state, and local requirements. Mention of commercial product names does not imply endorsement.

US EPA ARCHIVE DOCUMENT

APPENDIX B: EXAMPLE CALCULATION OF NUMBER OF TESTS REQUIRED

This appendix presents example calculations to illustrate calculation of the minimum number of tests for ETV.

The calculation is based on:

1) PM and NO_x hot-start FTP emissions measurement variability experience for a diesel emissions laboratory, which is a function of both the type of measurement and the emissions level. The emissions variability is taken to be known for the population of measurements. Therefore the normal distribution value is appropriately used in the calculations. Eq. B-1 is not strictly applicable for a set of measurements for which only sample standard deviations are available;
2) A known baseline mean emission; and
3) A mean controlled emission (the product of the baseline emission and the expected emissions reduction).

The criterion being used is that the minimum number of hot-start FTP tests required for ETV is the number of tests required to have a 90% probability of detecting the specified emission reduction at the 95% confidence level. The basic equation being used for the calculation is:

$$n \approx (z_\alpha + z_\beta)^2 [\sigma^2_1 + (1 - \delta/100)^2 \cdot \sigma^2_2] / \delta^2 \qquad \text{(B-1)}$$

where:

n	=	sample size in each group, rounded up to the next integer;
z_α	=	normal distribution value corresponding to upper-tail probability of α; and
z_β	=	normal distribution value corresponding to upper-tail probability of β.
$1-\alpha$	=	confidence coefficient on comparison of means (0.95 minimum for ETV);
$1-\beta$	=	probability of detection of reduction (0.90 minimum for ETV);
σ^2_1	=	squared standard deviation of baseline-engine emission data, expressed as a percent of the baseline emission value;
σ^2_2	=	squared standard deviation of controlled-engine emission data, expressed as a percent of the baseline emission value;
δ	=	difference between baseline and controlled engine emissions mean, expressed as a percent of the baseline emission value;

Note that σ_1, σ_2, and δ, are expressed as percentages of the baseline emission. This transformation was used to simplify the equation and allow its use for Table 1. For Table 1, the baseline emission value was chosen as the 1990 EPA certification value. The parameter 'z' is tabulated under different names in statistics reference texts. It is the 'z' value corresponding to 'the tail area of the unit normal distribution' in Box, Hunter, and Hunter (1978). In the Standard Mathematical Tables (CRC, 1968), 'z' is known as 'x', and the tail area is labeled '1 - F(x)', where F(x) is the cumulative distribution function of a standardized normal random variable. To obtain the value of 'z' from the statistical tables, α (or β) is the probability (ranging from 0.5000 to 0.0000) in the body of the table, and 'z' is read (or interpolated) from the appropriate column and/or row, ranging from 0.00 to 4.00 over that

US EPA ARCHIVE DOCUMENT

range. The value 'z' can be calculated within an EXCEL® or QUATTRO PRO® spreadsheet as the absolute value of the function returning the inverse of the standard normal cumulative distribution, NORMSINV(probability), by setting probability equal to α or β, as appropriate.

Table B-1 gives a step-by-step calculation example drawn from Table 1 for a 90% probability ($\beta = 0.10$) of detecting a 5% and a 50% emission reduction at the 95% confidence level ($\alpha = 0.05$).

Table B-1. Example calculation of minimum number of ETV tests.

	Table 1, Col.1	Table 1, Col. 3
Emission reduction relative to baseline (certification) emission, δ, %	5	50
Known measurement variability at specified emission reduction, σ_2, %	2	3
Known measurement variability for baseline engine, σ_1, %	2	2
α	0.05	0.05
z_α	1.645	1.645
β	0.10	0.10
z_β	1.282	1.282
$(\sigma^2_1 + (1 - \delta/100)^2 \cdot \sigma^2_2) / \delta^2$	0.304	0.0016
$(z_\alpha + z_\beta)^2 (\sigma^2_1 + (1 - \delta/100)^2 \cdot \sigma^2_2) / \delta^2$	2.61	0.014
Number of tests required[a], n	3	1[a]

Note: [a] The minimum number of ETV tests is three. If 'n' is less than three, 'n' equals three.

Substitution of the t-statistic for z in Equation B-1 implicitly violates some of the assumptions made in the derivation and is therefore not strictly valid. An iterative calculation results, and it may not converge. However, it does provide a number of tests estimate that is larger and closer to the result of the population statistics confidence interval described in Section 5.1.2.

US EPA ARCHIVE DOCUMENT

APPENDIX C: SENSITIVITY OF NUMBER OF TESTS CALCULATION TO MEASUREMENT VARIABILITY

Table C-1 presents the results of a sensitivity analysis of the calculation of the required number of tests in the particular cases of high (85%) and low (10% and 5%) reductions in emissions. The number of tests reported in the final column is the number required to have a 90% probability of detecting the emissions reduction with 95% confidence. The equation in Appendix B was used to compute the required number of tests. As in these sections, all calculations utilize the normal distribution under the assumption that the test measurement error is known and constant.

Within Table C-1, the variability of the baseline engine measurement ranges from 2 to 30%, and the controlled engine measurement variability from 10 to 30%. All of the percentage numbers in the table are referenced to a baseline engine emission. To convert the percentages to an absolute emission rate, they must be multiplied by a baseline engine emission rate, and at 30% variability the standard deviations are twice the emission rate in g/bhp-hr. The emissions and standard deviations in Table C-1 have all been calculated for a baseline engine emitting PM at the 1990 certification level of 0.6 g/bhp-hr. For example, from the first row, an 85% reduction means an absolute PM emission of 0.09 g/bhp-hr. A 10% controlled engine measurement variability means the standard deviation for that measurement is 0.06 g/bhp-hr. For the baseline engine, the variability is 2%, so the baseline engine standard deviation is 0.012 g/bhp-hr. The same approach can be used to make a similar table for any other emission rate by multiplying the percentages by the desired baseline emission rate.

While the number of required tests increases as the test variability increases, Table C-1 shows that the increase is modest at high emissions reduction levels. While higher variability is expected at higher levels of control because the absolute emissions concentrations are low, the large reduction in emissions is easily detected.

On the other hand, lower variability is expected for low emissions reductions, but the smaller changes are harder to detect and more tests are required. Therefore even modest variability levels (relative to those in the top block of Table C-1) lead to very large numbers of tests.

As was discussed in Section 5.1.2, calculation of the confidence intervals on the mean emissions reduction will be based on population statistics and will utilize the t-distribution. Thus the number of tests calculated using Equation B-1 (population statistics) may be fewer than will be required by the data itself based on sample statistics. As mentioned in Appendix B, an approximate calculation can be made for sample variability utilizing the Student's t-distribution rather than the normal (z-distribution) in Equation B-1. This use of Equation B-1 is not strictly valid, but may be useful for low emission reduction and/or high variability test designs to make a better estimate of the number of tests required.

1.0 INTRODUCTION

This protocol describes the Environmental Technology Verification (ETV) Program's considerations and requirements for verification of emissions reduction provided by fuel and lubricant technologies. For purposes of this protocol, all such technologies will be identified as fuel modifications (FMs). The basis of the verification will be comparison of the emissions and performance of well-maintained, conventionally fueled (or lubricated) engines or vehicles to the same engines or vehicles with FMs. The protocol applies to diesel- and gasoline-fueled engines and light-duty vehicles in mobile source applications and describes the requirements for a single engine or vehicle ETV having narrow application and for a multiple engine or vehicle ETV to evaluate fleet-wide emissions reductions.

ETV provides verified emissions reduction data for FM technologies. It may be part of an overall process that leads to inclusion of FMs on the U.S. Environmental Protection Agency (EPA) mobile sources retrofit emissions reduction verified technology list. This protocol describes the ETV portions of that process in detail. Table 1 provides an overview of mobile source FM ETV and its interface with the EPA retrofit emissions reduction program.

[c] EPA-ORD = EPA's Office of Research and Development, the ETV sponsor.

1.1 Environmental Technology Verification

EPA through its Office of Research and Development (EPA-ORD) has instituted the ETV Program to verify the performance of innovative and improved technical solutions to problems that threaten human health or the environment. EPA created the ETV Program to accelerate the entrance of new and improved environmental technologies into the marketplace. It is a voluntary, nonregulatory program. Its goal is to verify the environmental performance characteristics of commercially ready technologies through the evaluation of objective and quality-assured data so that potential purchasers and permitters are provided with an independent and credible assessment of what they are buying and permitting.

US EPA ARCHIVE DOCUMENT

The ETV Program does not conduct technology research or development. ETV test results are always publicly available, and the applicants are strongly encouraged to ensure prior to beginning an ETV test that they are satisfied with the performance of their technologies. Within the ETV Program, this state of development is characterized as "commercially ready."

The provision of high-quality performance data on a commercial technology encourages more rapid implementation of that technology and consequent protection of the environment with better and less expensive approaches. The ETV Program is conducted by seven ETV centers that span the breadth of environmental technologies.

1.2 Air Pollution Control Technology Verification Center

EPA's partner in the Air Pollution Control Technology Verification Center (APCTVC) is RTI International,[1] a nonprofit contract research organization with headquarters in Research Triangle Park, NC. The APCTVC verifies the performance of commercially ready technologies used to control air pollutant emissions. The emphasis of the APCTVC is currently on technologies for controlling particulate matter (PM), volatile organic compounds (VOCs), nitrogen oxides (NO_X), and hazardous air pollutants (HAPs) from both mobile and stationary sources. The activities of the APCTVC are conducted with the assistance of stakeholders from various interested parties. Overall, APCTVC guidance is provided by the Stakeholders Advisory Committee (SAC), whereas the detailed development of individual technology ETV protocols is conducted with input from technical panels focused on each technology area.

The APCTVC develops generic verification protocols and specific test/quality assurance (QA) plans, conducts independent testing of technologies, and prepares ETV test reports and statements for broad dissemination. Testing costs are ultimately borne by the technology applicants, although initial tests within a given technology area may be partially supported with government funds.

1.3 The APCTVC Mobile Sources Verification Program

The various retrofit technologies have been divided into three groups to facilitate ETV:

- Retrofit diesel mobile source control devices,
- FMs, and
- Selective catalytic reduction (SCR) devices.

Retrofit mobile diesel control devices include exhaust treatment emission control devices, other retrofit devices, and engine modifications. Some require no mechanical changes to engines, whereas others will involve some modification of the engine or its control system. Filters for PM control and diesel exhaust catalysts (DECs) may make use of or require some integration with engines. Engine modifications, in this context, refer to pollution reduction technologies integral to the engine or the engine control systems. All these technologies have the potential to affect engine performance, and the concurrence of the engine manufacturer that the changes are compatible with safe, efficient, and reliable operation in the engine is an important element in demonstrating commercial readiness and suitability for ETV. ETV of these technologies is guided by *Generic Verification Protocol for Diesel Exhaust Catalysts, Particulate*

[1]RTI International is a trade name of Research Triangle Institute.

US EPA ARCHIVE DOCUMENT

Filters, and Engine Modification Control Technologies for Highway and Nonroad Use Engines (RTI, 2002).

SCR NO_X control technologies are also retrofit technologies, but they require more integration with the controlled engine than most other retrofit devices and therefore are being treated as a separate category (for which a separate verification protocol is being developed).

This generic verification protocol (GVP) provides the requirements for APCTVC's verification of the performance of FMs applied to mobile source diesel and gasoline engines. Other organizations (e.g., EPA's Office of Transportation and Air Quality [EPA-OTAQ] and the California Air Resources Board) also verify the performance of FMs under different protocols to meet the needs of those organizations. The technology applicant should discuss the intended application of the FM with EPA-OTAQ to determine the most suitable path for verification.

This GVP is intended to apply only to FMs. The APCTVC reserves the right to evaluate each technology submitted for verification and to determine the applicability of this protocol to that specific technology. Regulatory authorities (EPA-OTAQ and others) may also have requirements. Special testing may be required in some cases to maintain the integrity and credibility and, therefore, the value of verifications. The critical data quality objectives (DQOs) in this document were chosen to provide emissions measurements sufficient to support the vendor's application for emissions credits under the Voluntary Diesel Retrofit Program (VDRP).

This protocol was developed and has been reviewed by a technical panel composed of a broad group of stakeholders who have expertise in mobile source controls and come from the vendor, user, and regulatory spheres. Technical panel membership is dynamic, and its composition is expected to change over time as technical emphases change. The APCTVC will maintain membership balance on the panel.

The basic FM verification will measure and report baseline emissions concentrations and rates using the Federal Test Procedures (FTPs) applicable to a particular engine or vehicle on a baseline fuel compared to that same engine or vehicle using the FM. The test requirements will differ depending on whether the FM provides its full emissions reduction immediately (immediate-effect FM) or requires operation for some period of time to reach full effect (cumulative-effect FM). The engines or vehicles required to be tested will depend on the intended use and applicability of the FM. The tests will be conducted at an independent, third-party testing organization that has been qualified and audited by the APCTVC. The data quality requirements of this GVP will be applied at approved testing organizations through the preparation of an FM-specific test/QA plan. Other laboratory-, application-, or technology-specific information may also need to be addressed in the test/QA plan, which is described in Section 10.0. Because specific technology areas may require special expertise or emphasis, input and review will be obtained from an ad hoc subcommittee of the technical panel and/or outside experts when deemed appropriate by the APCTVC. Test results will be presented as ETV reports and statements.

This generic protocol will be revised as necessary. Changes to the protocol will not affect products that have been verified. However, such changes will be reflected in test/QA plans not yet finalized regardless of the applicant's application status. Test/QA plans that are being carried out when a protocol change is enacted will be examined to determine whether any modifications must be made.

US EPA ARCHIVE DOCUMENT

1.4 Quality Management

Management and testing in the APCTVC program are performed in accordance with procedures and protocols defined by the following:

- EPA's ETV Quality and Management Plan (QMP) (U.S. EPA, 2002a or the QMP current at time of testing);
- APCTVC Quality Management Plan (RTI, 1998);
- *Generic Verification Protocol for Determination of Emissions Reductions Obtained by Use of Alternative or Reformulated Liquid Fuels, Fuel Additives, Fuel Emulsions, Lubricants, and Lubricant Additives for Highway and Nonroad Use Diesel Engines and Light Duty Gasoline Engines and Vehicles* (this document); and
- Test/QA plan prepared for each FM test or group of tests.

EPA's ETV QMP lays out the definitions, procedures, processes, interorganizational relationships, and outputs that will ensure the quality of both the data and the programmatic elements of the ETV Program. Part A of the ETV QMP contains the specifications and guidelines that are applicable to common or routine quality management functions and activities necessary to support the ETV Program. Part B of the ETV QMP contains the specifications and guidelines that apply to test-specific environmental activities involving the generation, collection, analysis, evaluation, and reporting of test data.

The APCTVC QMP describes the quality systems in place for the overall APCTVC. It was prepared by RTI and approved by EPA. Among other quality management items, it defines what must be covered in the GVPs and test/QA plans for technologies undergoing ETV testing.

Generic Verification Protocols are prepared to describe the general procedures to be used for testing a type of technology and to define the critical DQOs. The GVPs for retrofit air pollution control technologies for highway and nonroad use engines were written by the APCTVC with input from a technical panel and approved by EPA.

A test/QA plan is prepared for each test or group of tests. The test/QA plan describes, in detail, how the testing organization will implement and meet the requirements of the GVP. The test/QA plan also sets DQOs for any planned measurements that were not set in the GVP for a particular technology. The test/QA plan addresses issues such as the testing organization's management structure, the test schedule, test procedures and documentation, analytical methods, recordkeeping requirements, and instrument calibration and traceability, and it specifies the QA and quality control (QC) requirements for obtaining ETV data of sufficient quantity and quality to satisfy the DQOs of the GVP. Testing organizations will be audited by the APCTVC against the approved GVP and test/QA plan they are expected to follow. Section 10 of this GVP addresses requirements for the test/QA plan.

Because multiple testing organizations may be conducting the tests, the APCTVC will develop a prototype test/QA plan (not part of this GVP) for each type of technology to ensure comparability. This prototype will be customized by the testing organization to meet its specific implementation of the FTPs as defined in 40 Code of Federal Regulations (CFR) Parts 86 and 89, and the secondary measurements, subject to approval by the APCTVC and EPA-ORD. Testing arrangements that do not meet the requirements of the FTP will not be approved, and test instrumentation or test procedures that the APCTVC determines will compromise data reliability or comparability between testing organizations will not be approved.

US EPA ARCHIVE DOCUMENT

2.0 OBJECTIVE AND SCOPE

2.1 Objective

The objective of this GVP is to establish the parameters within which FMs to diesel or gasoline engines will be tested to verify their emissions control performance with uniform and consistent methods.

2.2 Scope

This protocol describes the considerations and requirements for ETV of emissions reduction by FMs. The FMs to which it applies are

- Alternative diesel and gasoline fuels,
- Reformulated diesel and gasoline fuels,
- Additives to standard diesel and gasoline fuels,
- Alternative lubricants for diesel- and gasoline-fueled engines, and
- Lubricant additives and systems for diesel- and gasoline-fueled engines.

Although FMs may achieve similar emissions reductions on many engines, each ETV test is conducted on and reported for the actual test conditions: engine (vehicle), base fuel, and FM test conditions. The base engine (vehicle) will be well maintained and will produce emissions at levels consistent with a well-maintained engine (vehicle) of its age and use. FMs may be combined with other technologies for verification testing as a single entity emissions control system. Before systems can be accepted for verification,

- the controlling interests in each technology must be in agreement to pursue ETV (in this context, low sulfur diesel fuels are considered commodities available to all, not technologies, and therefore no permission is required),
- the applicant must be a single organization with authority to pay for the applicant's cost, and
- the applicant must show that each component of the system has a credible impact on emissions.

Verification testing for a system will incorporate into the test/QA plan elements from the protocols applicable to the individual technologies. In general, the test for a system will include the more stringent aspects of each protocol where they differ. Each test may be different, and the APCTVC should be consulted for assistance.

For purposes of ETV, the emission reduction effects of FMs are classified as either of two types:

1. Immediate effect—FMs whose emissions reduction effect is immediate for a well-maintained, base-fueled engine. No long-term residual effect is expected from an immediate-effect FM. The applicant agrees and the test confirms that reproducible results can be obtained for both the base and FM fuels on the same engine with an alternating fuel test pattern, allowing only for fuel flushing and a brief stabilization period (as many as three preconditioning cycles [EPA Urban Dynamometer Driving Schedule 40 CFR 86.132-90] for a light duty vehicle (LDV) and 1 hour of engine operation for a diesel) between tests.
2. Cumulative effect—FMs that require more than 10 hours of engine operation for a diesel or 500 miles of driving for a LDV on the FM for the product to reach its full effectiveness. Cumulative-effect FMs are expected to have residual effects on the test engine, and repeated base-fueled tests

US EPA ARCHIVE DOCUMENT

separated by FM tests would not be meaningful. Return to base fuel emissions rates is expected only after an extended period of operation or manual cleaning and rebuild.

FMs may be evaluated based on either of these categories. The applicant's requests and the product's performance mechanism will be considered. For example, an applicant may have a fuel additive that reaches its full potential only after an extended period of time, but the applicant may prefer to evaluate the additive with the immediate-effect procedure. The applicant must recognize and accept the implied liability for selecting the appropriate test program.

Emissions testing under this protocol is based on the FTPs for emissions certification of diesel highway engines (40 CFR Part 86), diesel nonroad engines (40 CFR Part 89), and light duty gasoline engines (40 CFR Part 86). For diesel nonroad engines, emissions testing under this protocol will also include the nonroad transient test cycle as published in the NPRM (Notice of Proposed Rulemaking) for "Control Emissions of Air Pollution from Nonroad Diesel Engines and Fuel" on May 23, 2003. (New test procedures become standardized and are incorporated into the FTPs from time to time. Verifications are to be conducted under the current applicable FTP.)

2.3 Applicability

2.3.1 Applicability of ETV Results to Other Engines and Engine Families

The basic ETV test remains the same for all FMs and engines; however, the FMs may interact differently with the various engines. The extension of emissions reductions from one engine or engine family to another requires engineering analysis of the data and may require additional testing. Determination of the applicability of single-engine tests to other engines is an EPA-OTAQ decision and not part of ETV.

2.3.2 Relationship of ETV Program to EPA-OTAQ VDRP Verified Technology List

EPA-OTAQ is charged with establishing a verified list of technologies capable of providing emissions reductions. The test results EPA-OTAQ will use to evaluate a technology may be generated following the ETV process, with the ETV report and verification statement submitted by the vendor as the data package to EPA-OTAQ. Other paths to the verified technology list also exist. The VDRP program is described and appropriate contacts are identified at http://www.epa.gov/otaq/retrofit/. The technology applicant should discuss the intended application of the technology with EPA-OTAQ to determine the most suitable evaluation path for the applicant's technology.

2.3.3 Assignment of Emissions Benefits to FMs

The emissions from engines vary as engines age and progress through the cycle of routine maintenance. The intent of ETV under this GVP is to determine the emissions reductions provided by FMs, exclusive of oil and filter changes, engine tune-ups, and similar scheduled maintenance that, by themselves, may provide emissions benefits. Emissions benefits may also accrue from tuning an engine to lower power output or other operating points different from those recommended by the engine manufacturer. The ETV test will be designed to isolate the effects of the FMs from coincident engine adjustments and tune-ups to the extent possible. Baseline engines will be tuned and set to the engine manufacturer's recommendations, and the baseline emissions are expected to be consistent with the age and usage history of the engine (near certification levels for diesel engines; in conformance with the expected model year standard for gasoline vehicles).

US EPA ARCHIVE DOCUMENT

Engine modifications may be appropriate for particular FMs that have different energy contents than standard fuels, and these will be implemented on the required test engines provided they are part of the description of the FM as a single technology.

2.4 Data Quality Objectives

The data of primary interest in this verification are the reduction in emissions of the FTP primary pollutants: NO_X, hydrocarbons (HCs), PM, and carbon monoxide (CO). The DQOs of this GVP are the requirements of the test methods specified in 40 CFR Part 86 (light duty gasoline and diesel highway engines) or 89 (nonroad diesel engines) when conducting the number and type of FTP tests called for by the approved test/QA plan for the FM. ETV tests that do not meet the FTP QA requirements are invalid.

The number and type of FTP tests (cold- and/or hot-start) required for ETV is determined from the following criteria:

First, a minimum of three tests is required to provide the basic ETV result of a mean emission reduction and the 95% confidence interval on that mean based on measured variability for each of the measured emissions and test parameters. For highway engines this minimum is satisfied with one cold start test and three hot start tests. For nonroad engines three replicates of the appropriate test sequence (i.e., three 8-mode tests, or three 6-mode tests) are required. A three test minimum is currently the same as is required by the State of California for its program.

Second, additional tests may be required to meet the ETV requirement that the test/QA plan provide a 90% probability of detecting the expected emissions reductions when computed using the expected experimental errors for the various measurements. These criteria become controlling for low emissions reductions and/or high test variability. This is a planning requirement for the test/QA plan. The procedure to determine the appropriate number of tests is given in Appendix B.

Third, additional tests may be desired by the applicant to reduce the width of the 95% confidence interval on the mean emission reduction. Section 5 provides additional explanation and example scenarios. This third criterion is a consequence of applying standard statistical procedures to the ETV test design and data analysis. At a fixed measurement variability, normal statistical procedures lead to a small number of tests giving a broader 95% confidence interval than a larger number of tests. To any regulator or potential technology user, an emission reduction of 40% ± 5% is better than 40% ± 20% and will be given more credence.

Noncritical measurements, including carbon dioxide (CO_2) emissions, fuel utilization, and power, will also be made as described in later sections. These are not considered critical, and the methods and DQOs will be stated in the test/QA plan.

The FTP tests referenced above are conducted following test cycles specified in 40 CFR. As discussed in Section 5, other test cycles may also be required for verification of an FM. A single test data set would consist of a single FTP test cycle and any other special cycle required for the FM. The requirements for the emissions tests remain the same in both cases.

An applicant may conduct privately sponsored tests at a testing organization for development purposes with the same test engine prior to or after conducting verification tests. Such testing is understood to be

US EPA ARCHIVE DOCUMENT

common and important to ensure the technology is properly adjusted and tuned to the application. The ETV data quality objectives do not apply to privately sponsored testing. However, the applicant and testing organization must coordinate the entire testing effort with the APCTVC so that:

- Preparation for the ETV test (submittal of the technology to the APCTVC, discussion of engine selection, and preparation of the test/QA plan) is completed prior to conducting the ETV test itself;
- The APCTVC is notified of the ETV test dates in time to schedule QA activities at the discretion of the APCTVC; and
- Declaration of the test run that is to be the ETV test is made prior to starting the test, the engine must be brought to a starting point in accordance with the test/QA plan, and the results of that test are documented and reported in accordance with the test/QA plan.

An applicant may desire to run the base-fueled ETV test, conduct private developmental testing, and then complete the ETV tests following the private testing. This approach may be acceptable provided the base-fueled run is considered to remain valid for the duration of and for the activities that occur during the private testing. If not, the base-fuel case will have to be rerun.

The data from all ETV tests will be retained and reported to the APCTVC, including invalid FTP test results. Data that meet the QA requirements of the FTP are considered valid and will be used to compute emissions reductions for ETV purposes.

The FM emissions reduction performance will be reported as both absolute emissions in the appropriate units (per applicable FTP) for the base-fueled and FM-fueled cases, and as percentage emissions reduction for a specific engine or engine family. The percentage emissions reduction reported will be the mean emissions reduction (relative to the baseline emission) with attendant upper and lower 95% confidence limits on that mean.

3.0 ETV RESPONSIBILITIES

The primary responsibilities for each organization involved in the FM ETV verification program were summarized in Table 1. Additional comments are provided below:

- The technology applicant provides the complete, commercially ready product for ETV testing, and logistical and technical support, as required, during the ETV testing. The applicant's responsibilities are defined by a contract or letter of agreement with the APCTVC (RTI.) The preliminary application (Table 1, Row 1) provides relevant background data and technology information to facilitate test/QA plan development. The applicant must pay the portion of the verification cost required at the time its contractual relationship with the APCTVC begins.
- In addition to the items in Table 1, the APCTVC prepares the GVP (this document); qualifies, approves, and audits the testing organization; provides a template for test/QA plans; prepares the ETV reports and statements from the laboratory test reports; and, jointly with EPA-ORD, reviews and approves the ETV reports and statements.
- Qualified testing organizations conduct ETV verifications under contract to the APCTVC. The order of activities in Table 1 is mandatory, with the test/QA plan being prepared and approved before testing. The testing organization also conducts internal QA on test results and reports.

US EPA ARCHIVE DOCUMENT

4.0 APPLICATION AND TECHNOLOGY DESCRIPTION

The ETV applicant is the basic source of information regarding its technology, information which is provided to the APCTVC and EPA-OTAQ through an application form. This information is used by the testing organization and APCTVC to prepare and review a test/QA plan that meets the requirements of the applicant and by EPA-OTAQ and other users to verify data. In keeping with the voluntary nature of ETV, the applicant must control the technology within the United States to submit it for verification.

For the applicant's convenience, the application form used by the EPA-OTAQ retrofit program can also be used for ETV. The applicant should complete as much of the form as possible and submit it to OTAQ and the APCTVC. ETV will provide test data that will allow completion of the form for submission to EPA-OTAQ and participation in the VDRP. The form can be obtained from the APCTVC and is also posted on the EPA-OTAQ retrofit website at http://www.epa.gov/otaq/retrofit/retrofittech.htm. Both Microsoft Excel and Lotus 123 versions are provided. Alternatively, an applicant who is not participating in the VDRP can use the APCTVC's shorter general application form.

The VDRP application consists of four worksheets: (1) Manufacturer Information, (2) Product Information, (3) Test Information, and (4) Component Information. There is a separate spreadsheet containing directions and examples for completing the forms. This guidance document begins with a page of general instructions for the entire form. Since no general form can anticipate the data requirements for all possible FMs, the applicant should use the applicable portions of the form. Additional information will be requested to supplement this form if needed.

The mobile sources ETV program is intended to provide independent and quality-assured performance data to potential users of technologies through a documented public process. Existing data (whether Confidential Business Information [CBI] or not) cannot be used to substitute for ETV tests, although they can be used to help design the ETV test. The ETV documents (protocol, test/QA plans, reports, and verification statements) are publicly available. For these reasons, the submittal of CBI to the APCTVC is unlikely to be necessary. The application form **is not** intended to convey CBI to the APCTVC and none should be included in the form. Any applicant who believes that CBI is required to provide input to the ETV process should explain that belief in a cover letter to the APCTVC. It should be noted that all information submitted on the application is subject to the Freedom of Information Act.

4.1 Manufacturer Information

This first page of the application requests background and contact information for the applicant who is seeking product verification. Guidance and examples supporting its use are provided on the second page of the guidance form.

4.2 Fuel Modification Descriptive Information

The second page of the application is used to describe the FM fully and concisely. It will be used to prepare the test/QA plan and as a more complete description of the technology in the ETV report. It requires a concise (300-word or less) description of the FM being verified and requests a number of operating details that summarize the emissions control performance expected, along with the product's operation. All questions may not apply. Instructions for completing this page can be found in the "Explan_Prod" page of the guidance document.

Item E 000095

US EPA ARCHIVE DOCUMENT

In the case where combinations of independent technologies are being submitted for verification, the description of the combined technology should completely identify and describe those technologies being combined and fully state the nature of the combined test and expected result.

4.3 Test Information

Results of verification testing on the applicant FM are to be detailed on the third sheet of the application form. Completion of this page is not required for application to the APCTVC for verification of a technology because the verification itself will be providing the test results. However, the applicant is encouraged to report all available test data, which can be used by the APCTVC to better plan the ETV test program for the applicant's technology. These existing test data will not be included in the verification report. The Explan_Tests page of the guidance document provides information for completing this page.

4.4 Component Information

The last page of the application form, Component Information, lists the major components of the technology system. For fuels and fuel additives, it is expected that few components will need to be listed here, although for combined systems this will be an important document. Directions are given in the Explan_Components page of the guidance.

5.0 ETV TESTING

This section gives the test requirements for verification of FMs. It also describes reduction of the data to produce the emissions reduction measures that are the product of the tests. Section 5.1 gives an overview of the testing and data analysis as it applies to all FMs. Section 5.2 gives ETV testing details for FMs intended for use in diesel engines. Section 5.3 gives the detailed test requirements for ETV of FMs intended for use in gasoline vehicles and engines. Section 5.4 gives detailed test requirements for ETV of lubricants.

5.1 Test Design and Data Analysis for ETV of FMs

5.1.1 Overview of Testing Requirements

The data of primary interest in this verification testing are the reduction in emissions of NO_X, HC, PM, and CO. Emissions reductions are defined as the percentage reduction obtained between a base case and the FM candidate case or the natural log equivalent. For all engine and vehicle types, emissions measurements are made using the FTP certification test cycles applicable to the engine or vehicle for which the FM is intended. Additional special test cycles are sometimes also required in addition to the FTP certification test. The details of the tests are different for different engines and vehicles and are given below.

A simple test of an engine without a control device installed followed by one with the device installed is not considered to be adequate for all FM ETVs. Emissions from engines or vehicles may increase over their service life, particularly for gasoline-fueled engines or vehicles. FMs may require significant service life to have their full effect. These characteristics require that the ETV test for FMs be designed to provide emissions reductions with a changing baseline emission.

US EPA ARCHIVE DOCUMENT

Testing conducted under this protocol utilizes individual FTP and special tests that measure emission rates, *E*, of various pollutants. Replicate tests are conducted at a particular test point in the service life of an engine or vehicle, fueled or lubricated by either the base or the FM candidate. The FTP and special tests are combined to give a combined emissions rate for each pollutant. The complete ETV test sequence includes several test points, each of which gives a combined emissions rate for either the base engine or the candidate FM engine. The combined emissions rates from all valid data are then used to estimate the emissions reduction, *ER*, for each pollutant.

The requirements for testing diesel and gasoline FMs for immediate and cumulative effects in highway and nonroad diesel applications will be discussed in greater detail in the following sections. Table 2 summarizes the tests required at each test point in the test sequence.

ETV provides engine emissions reductions from which EPA-OTAQ or others estimate fleet emissions reductions. Estimation of fleet-wide emissions reductions from single engine emissions reductions requires knowledge of the composition of the entire fleet, identification of the number and kind of representative engines or vehicles, and numerous other assumptions. All of these considerations factor into the experimental design. Making these assumptions is uniquely the responsibility of the agency evaluating the data.

Table 2. Summary of Tests Required at Each Test Point

Type	Effect	Engine	Sequence of Test Points[1]	Tests at Each Point[2]	Reference
Diesel FMs	Immediate	Highway	BCCB or BCBC	(Cold + 3 hots + SET)	5.2.3.4, 5.2.4.1
Diesel FMs	Immediate	Nonroad	BCCB or BCBC	3 (multi-mode steady-state) + NTTC[3]	5.2.3.4, 5.2.4.1
Diesel FMs	Cumulative	Highway	BBBBCCBB	(Cold + 3 hots + SET)	Fig. 1, 5.1.3.4
Diesel FMs	Cumulative	Nonroad	BBBBCCBB	3 (multi-mode steady-state) + NTTC	Fig. 1
Gasoline FMs	Immediate	Highway	BCCB	3 (Cold + hot + US06)[4]	5.3.3.2, 5.3.4
Gasoline FMs	Immediate	Nonroad	BCCB	3 (multi-mode steady-state)	5.3.3.2, 5.3.4
Gasoline FMs	Cumulative	Highway	BBBBCCBB	3 (Cold + hot + US06)[4]	5.3.3.2, 5.1.3.4
Gasoline FMs	Cumulative	Nonroad	BBBBCCBB	3 (multi-mode steady-state)	5.3.3.2, 5.1.3.4
Lubricant FM	*(diesel)*	Highway	BBBBCCCCBBBB	(Cold + 3 hots + SET)	Fig. 2, Table 7
Lubricant FM	*(diesel)*	Nonroad	BBBBCCCCBBBB	3 (multi-mode steady-state) + NTTC	Fig. 2, Table 7
Lubricant FM	*(gasoline)*	Highway	BBBBCCCCBBBB	3 (Cold + hot + US06)	Fig. 2, Table 7
Lubricant FM	*(gasoline)*	Nonroad	BBBBCCCCBBBB	3 (multi-mode steady-state)	Fig. 2, Table 7

[1] B = Baseline condition; C = Candidate technology.
[2] Minimum requirement. When emissions reductions are expected to be low, more tests may be required to achieve the 95% confidence interval.
[3] Nonroad transient test cycle.
[4] Highway fuel economy test, cold CO, and evaporative emissions testing will be required on any FM that may reasonably be expected to affect fuel volatility.

5.1.2 Test Design Requirement for Single Engine Verification

Minimizing the cost of ETV testing is important, and limiting the amount of testing required is one way to lower costs. However, if too few tests are conducted, normal experimental variability could prevent the ETV from finding a significant result. All ETV test/QA plans for FMs are required to include

US EPA ARCHIVE DOCUMENT

sufficient tests to have a high probability of detecting the emissions reductions expected by the applicant. In addition to other requirements, each FM ETV test plan is to be designed to have at least a 90% probability of detecting the emission reductions expected by the applicant. This requirement was adopted to ensure, as much as practical, that the ETV test would accomplish the applicant's goals.

In this context, detecting means that the 95% confidence interval on the emission reduction does not include zero. (This requirement is for test design purposes and does not require that the test/QA plan be modified should actual test data show that the assumptions that went into the calculation were incorrect. However, insufficient replication can result in the inability to verify any emissions reduction and publication of an ETV report stating that a technology had no statistically significant benefit.) The test/QA plan prepared for the FM will reflect this requirement, based on the applicant's knowledge of his product and the testing organization's estimates of test variability.

At each test point, a minimum of three tests are required. More may be necessary for low emission reduction technologies. The definition of a single test depends on the technology. For diesel engines, for instance, one FTP cold start, three FTP hot starts, and one additional cycle are considered three tests when combined. Depending on the FM technology and test engine or vehicle, a complete single engine ETV may require as few as two or as many as 12 base and FM test points. Sections 5.2 (diesel engines), 5.3 (gasoline vehicles), and 5.4 (lubricants) provide the details of these requirements.

5.1.3 Analysis of Combined Emissions Data

5.1.3.1 Data analysis for single engine tests of immediate effect FMs. Immediate effect FMs produce their emission reduction as soon as they are fully flushed through the fuel system and are expected to have no residual effect. The emissions reduction can therefore be determined without concern for test engine drift or deterioration. Verification of immediate effect FMs requires a single base case test point followed closely in time by a single candidate FM test point and is very similar to that used to test retrofit devices. This section describes the data analysis procedure that will be used to calculate the emission reductions for immediate effect FMs.

The first steps are the calculation of the combined test emission results for each test and each pollutant for the base and candidate FM tests. E_B and E_F are understood to refer to a single pollutant in the equations below. Calculation of E_B and E_F from individual test results differs for diesel and gasoline engines and for LDVs and is described in the respective sections below. Once the E values for the test points are available, the sample means and standard deviations (s_B and s_F) are computed using Equations 1 and 2.

$$\overline{E_B} = \frac{\sum_{1}^{n_B} E_{B,i}}{n_B} \qquad \textit{and} \qquad \overline{E_F} = \frac{\sum_{1}^{n_F} E_{F,i}}{n_F} \tag{1}$$

where:

$\overline{E_B}$ = mean emission rate for base for a single pollutant,
$\overline{E_F}$ = mean emission rate for FM for a single pollutant,
$E_{B,i}$ = emission results for a single base (B) test for a single pollutant,
$E_{F,i}$ = emission results for a single FM (F) test for a single pollutant,

US EPA ARCHIVE DOCUMENT

n_B and n_F = number of base (B) and FM (F) tests, and
s_B and s_F = standard deviations of base (B) and FM (F) tests.

$$s_B = \sqrt{\sum_{1}^{n_B}\left(E_{B,i} - \overline{E_B}\right)^2 \Big/ \left(n_B - 1\right)} \quad and \quad s_F = \sqrt{\sum_{1}^{n_F}\left(E_{F,i} - \overline{E_F}\right)^2 \Big/ \left(n_F - 1\right)} \tag{2}$$

The raw emission reduction for each pollutant, ER_{RAW}, is then computed as the difference between the combined emission results for the base and candidate FM case, divided by the base case emission, as shown in Equation 3.

$$ER_{RAW} = \left(\overline{E_B} - \overline{E_F}\right) \Big/ \overline{E_B} \tag{3}$$

The upper and lower bounds of the approximate confidence interval (*CI*) around ER_{RAW} are computed using Equations 4a and 4b.

$$CI\ (upper\ bound) = ER_{RAW} + \left\{ \left(t_{\alpha/2} \bullet \sqrt{\frac{s_B^2}{n_B} + \left(1 - ER_{RAW}\right)^2 \frac{s_F^2}{n_F}} \right) \Big/ \overline{E_B} \right\} \tag{4a}$$

$$CI\ (lower\ bound) = ER_{RAW} - \left\{ \left(t_{\alpha/2} \bullet \sqrt{\frac{s_B^2}{n_B} + \left(1 - ER_{RAW}\right)^2 \frac{s_F^2}{n_F}} \right) \Big/ \overline{E_B} \right\} \tag{4b}$$

where $t_{\alpha/2}$ is $t_{0.025}$ in tables of the critical values (alternatively, tail area probability) of the t-distribution, with degrees of freedom, *v*, given by Equation 5 (rounded down):

$$v = \frac{\left[s_B^2 / n_B + \left(1 - ER_{RAW}\right)^2 s_F^2 / n_F \right]^2}{\left[\left(s_B^2 / n_B \right)^2 / \left(n_B - 1\right) \right] + \left(1 - ER_{RAW}\right)^4 \left[\left(s_F^2 / n_F \right)^2 / \left(n_F - 1\right) \right]} \tag{5}$$

The fractional values of emission reduction and the confidence intervals are converted to percentages by multiplying by 100%.

Although ER_{RAW} is the observed value of the data for the single engine tested, there is significant potential for the true emission reduction achieved in the field to be lower due to measurement errors. Therefore, an environmentally conservative discounted single engine emission reduction, ER_{DSCT}, is also reported as the lower bound of the confidence interval using Equation 6.

$$ER_{DSCT} = 100\%\ CI\ (lower\ bound\ from\ Equation\ 4b) \tag{6}$$

For example, if ER_{RAW} was 0.15 (15% emissions reduction) with a confidence interval of ± 0.05 (± 5%), ER_{DSCT} would have a value of 0.1 (10%).

US EPA ARCHIVE DOCUMENT

5.1.3.2 Calculation of fleet-wide emissions reductions for immediate effect FMs. For immediate effect FMs, the fleet emissions reduction (ER_{FLEET}) is computed by EPA-OTAQ for gasoline engines as the unweighted (gasoline) mean or as the weighted mean (diesel engines) of the discounted single engine emissions reductions. Emissions reductions are computed separately for each pollutant.

5.1.3.3 General treatment of cumulative effect FMs. ETV of cumulative effect FMs requires additional testing. Because the technology must be in use for an extended period to take full effect, the total duration of the testing can be long. Therefore, the base engine emissions may change as the engine/vehicle ages, or because ambient conditions change, or because test cell instrumentation requires recalibration. This situation leads to uncertainty about the cause of a measured emission change. Cumulative effect technologies also have a residual effect after use ceases. This characteristic prevents immediately re-running the baseline at the end of the test to quantify any drift.

Figure 1 illustrates the expected FM performance and testing model used in this protocol to evaluate a cumulative effect FM having residual effects on emissions. Increasing emissions with increasing service is assumed based on the known behavior of gasoline vehicles and their catalytic emissions control systems. Over the life of the vehicle, the emissions steadily increase as shown by the solid line, which represents the base case. Some of the deterioration is caused by changes in the engine, and some is caused by the emissions control system's deterioration. The slope and intercept of the deterioration line varies from gasoline vehicle to gasoline vehicle and from within and across vehicle's type and manufacturer. For the purposes of this protocol, the deterioration factor is assumed to be linear and unknown. Over the service life of diesel engines (when not controlled by catalytic systems), the deterioration factor is low and may be zero within the time frame of ETV tests. After changing to the candidate FM, the emissions are assumed to become lower. The shape of the curve during the transition is not important to this analysis.

The goal of the cumulative effects testing and data analysis is to separate the change in emissions due to the FM from the other changes. The emission reduction is assumed to be proportional to total emissions. That is, regardless of total emissions, the percent emissions reduction is assumed constant as implied by the natural log transformation of the emissions rate (vertical scale in Figure 1). As shown in Appendix C, the use of a log-scale analysis produces results nearly identical to using a percentage change in the native units when the measurement errors and effects to be detected are relatively small. The analysis is thus conceptually consistent with that for an immediate-effect FM.

US EPA ARCHIVE DOCUMENT

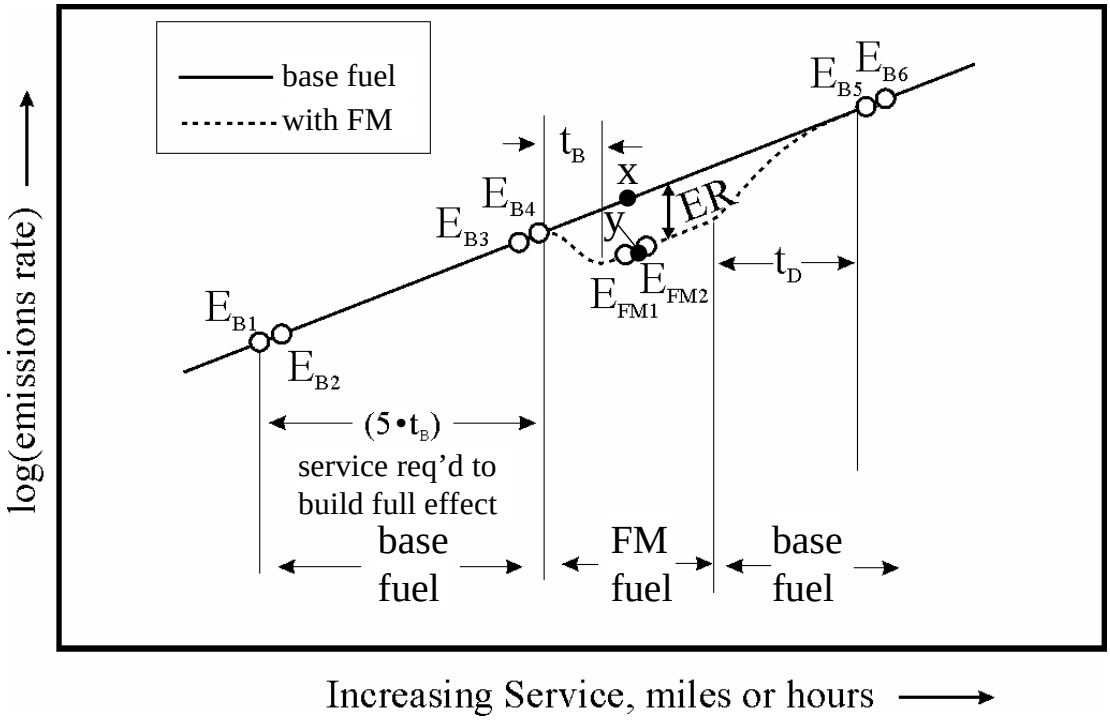

Figure 1. Performance Model and Testing for Cumulative Effects FMs

The candidate FM is assumed to be characterized by a known time for the emissions reduction to have full effect, t_B. Determining t_B is not part of this protocol and is assumed to be known and specified by the applicant. As shown in Figure 1, the test procedure requires a run-in period equal to five times t_B. The service accumulation cycle is required to be appropriate for the engine/vehicle (40 CFR 86.090-26), to be the same for both base fuel and candidate FM, and for an entire cycle to be completed before beginning a test sequence. Figure 1 shows two base case emissions test sequences carried out in duplicate at the beginning (E_{B1} and E_{B2}) and end (E_{B3} and E_{B4}) of the run-in period to provide a good estimate of the deterioration rate. FMs in diesel engines may not require both.

Following the completion of emissions test sequence E_{B4}, the FM fuel is flushed through the system, and a period of operation on candidate FM fuel begins. Use of candidate FM fuel continues for the period t_B, after which two FM test sequences, E_{FM1} and E_{FM2}, are carried out. Once E_{FM2} has been determined, the engine/vehicle is returned to base case fuel. The base fuel is used for the period required to return the engine to the base emission line. This time period, t_D, is also assumed to be known and specified by the applicant before ETV testing, and determination of t_D is not part of the ETV test. After operating on base fuel for the time required for the effect of the FM fuel's use to completely decay, the fifth and sixth base case emissions sequences are carried out to obtain E_{B5} and E_{B6}, which confirm the deterioration line.

Although the verification process does not require testing beyond point E_{B6}, the applicant may wish to generate additional data if the FM is expected to provide a benefit that would not be fully evaluated through a single FM test period, or to evaluate different pollutants or increase confidence in results. In keeping with ETV procedures, all verification testing must be planned and included in the test/QA plan.

The ETV test must be conducted in the order shown in Figure 1: base, candidate FM, base. Before all testing, the engine must be conditioned on the test fuel (base or candidate) to purge any remaining old

US EPA ARCHIVE DOCUMENT

fuel before each map or cold start procedure. The reference cycle map used for the candidate diesel fuel must be the same as determined for the base fuel. The oil and oil filter are to be changed immediately prior to test sequences E_{B1}, E_{FM1}, and E_{B5}.

The data analysis of the cumulative effect FMs described in the following sections is based on an assumption that Figure 1 represents the true behavior of FM, with t_B and t_D known so that there is no confounding between the base and FM fuel cases. These procedures are those recommended and preferred by EPA-OTAQ.

Because the data analysis approach in this protocol is specific to the technology performance and experimental design assumed in Figure 1, an applicant may propose a verification applying another experimental design. In this case, the applicant's proposal must include a detailed justification and demonstrate quantitatively its superiority to the ETV protocol's approach; the applicant's proposal will be evaluated and tested by ETV statisticians regarding the reasonableness of the design and the engine/vehicle selection. The test/QA plan will include an appendix describing development of the experimental design to be used for testing.

5.1.3.4 Data analysis for single engine cumulative effect FMs. The emission reduction is computed from the two FM measurements (E_{FM1} and E_{FM2}) and from the estimated base emissions at the same service (hours or miles). In Figure 1, this would be the intersection of a vertical line rising between E_{FM1} and E_{FM2} and the base case performance line (i.e., difference in rates at points X and Y). The base fueled emissions at that point are estimated from a linear least-squares regression of the natural logarithm of emissions [ln(E)] versus service accumulation for the six base case emissions measurements (E_{B1}, E_{B2}...E_{B6}). Appendix D develops this approach to analyzing the data, presents equations that allow calculation of the estimated effect of the FM and the variance of that estimate, and provides some suggestions to maximize the power of the experiment.

5.2 ETV Testing for Diesel FMs

This section applies to FMs used in compression-ignition engines.

5.2.1 Diesel Base Fuels

Applicants may choose from among the following two FM base fuel alternatives, which are described in more detail in Table 3:

1. The nationwide average base fuel for nationwide application of the FM.
2. FMs intended for California (or an area in which California-type fuel is the dominant available diesel fuel) may be tested using California-type fuel as the base fuel.

Applicants who intend to market FMs in specific markets (regional, specific, or other) may propose alternate base fuels for use during ETV testing. A proposal for an alternate base fuel must be accompanied by evidence that the fuel truly is a "base" that is in use and from which the candidate FM will reduce emissions. If acceptable, the fuel supplied by the applicant will be tested and reported as the base fuel in the ETV report and statement. ETV can make no representation regarding possible extension of the data to other base fuels.

In all these cases, the ETV report and statement will report the test conditions, the FM tested, and the results obtained.

US EPA ARCHIVE DOCUMENT

Note that the ranges given in Table 3 for the properties of the base fuels are not as broad as those for the fuel allowed in emissions certification tests, and that the sulfur level has been limited to 15 ppm. The ranges were narrowed to reduce test-to-test variations in the emissions reductions measurements, whereas the ultra-low sulfur diesel (ULSD) is proposed as the test case. Refinery diesel product streams must be used to produce the base fuels for tests. They cannot be blended from purified chemicals. Because oxygenates are rarely used in diesel, neither the California nor the national average fuel may contain oxygenates. Although additives are not used consistently in diesel, it is permissible for the California and/or the national average fuel to contain a registered additive or additives designed to maintain fuel quality during transport and storage, such as an antioxidant and/or corrosion inhibitor.

Table 3. Properties of Base Fuel for ETV of Diesel FMs

Property	Nationwide Average Fuel	California Fuel	Applicant-Choice Base fuel[a]	ASTM Test
Accepted by EPA-OTAQ	Yes	Yes	No[a]	
Cetane number	43 to 46	51 to 54		D 613
Aromatics, volume %	32 to 36	20 to 24		D 5186
Specific gravity	0.84 to 0.86	0.83 to 0.85		D 1298
Additives	minimal[b]	minimal[b]		
Sulfur, ppm				
Highway	0 to 15	0 to 15		D 6428
Nonroad	2500 to 3500[c]	100 to 160		D 2622
Distillation range				
10% point, °F	410 to 430	410 to 430		D 86
50% point, °F	490 to 520	490 to 520		D 86
90% point, °F	585 to 620	595 to 630		D 86

[a] Testing of FMs using a base fuel chosen by the applicant is possible within this protocol.
[b] Cetane improvers and some other additives cannot be avoided in refinery products. However, these are to be minimized, and no additional additives are to be used.
[c] Use of highway diesel sulfur levels allowed in accordance with 40 CFR part 89.330.

5.2.2 Selection of Engines for ETV Testing

The applicant may select one of three targets for the candidate diesel FM: (1) a specific engine family as represented by a single test engine, (2) the entire on-highway diesel fleet, or (3) some portion of the on-highway diesel fleet. A candidate FM ETV can be conducted on any single engine meeting the requirements of Section 5.2.2.1.

5.2.2.1 General criteria for diesel engine selection. Test engines must be in good operating condition and representative of in-use engines. Standard engines proposed for testing must be in a certified configuration. The engines are to be "as delivered, without any added technologies, and are to be tuned to the manufacturer's specifications. (Specially prepared engines [such as future technology engines that are not commonly available] may also be tested under this protocol, and will be identified as such. However, the acceptability of such a verification to EPA-OTAQ should be explored by the applicant prior to beginning verification if VDRP listing is desired.) For engines manufactured before implementation of emission standards, the engine must be representative of normal production engines.

US EPA ARCHIVE DOCUMENT

Engines must have a minimum of 125 hours of use before beginning an ETV test and exhibit stable operation. Emissions control components must be sufficiently broken in so that they exhibit stable operation over the course of the test program. Because residual effect FMs may have been used in an engine before its use in the ETV program, the engine owner (testing organization or applicant) must establish that the engine can be considered a reasonable baseline for the engine family of interest, either through replicate baseline tests showing a stable baseline or documentation of its fueling history. On the base fuel, the test engine must not exceed 110% of its applicable emission standards. For engines manufactured before emission standards, the engine must not exceed 150% of the first standards for that engine category.

Rebuilt engines will be allowed so long as they represent a certified configuration, produce emissions at the certification standard when fueled by the base fuel (within limits given above), and meet other applicable criteria.

5.2.3 Test Procedures—General Requirements

5.2.3.1 Engine maintenance. All equipment used in the testing must be maintained and operated in accordance with applicable FTP regulations. To the extent practical, the engine and test conditions should be maintained the same between the base and candidate FM tests. This consideration applies to all aspects of engine operation and maintenance. Routine engine maintenance must be performed before beginning a verification test and, once testing has started, routine engine maintenance is not allowed. If use of an FM requires that an engine be tuned for the fuel, this requirement must be detailed in the test/QA plan and will be included in the report as a requirement for use of the FM. Resumption of testing following engine or test stand breakdown and repair will be evaluated by the APCTVC on a case-by-case basis and will be allowable only for brief shutdowns for which no emissions impact is considered likely. A full fuel analysis is required on both base and candidate FM fuel.

5.2.3.2 Test data format and retention. Raw test results will be retained by the testing laboratory in the electronic format required for EPA certification tests and made available to the APCTVC on request. Results for cold and hot starts will be reported both independently and appropriately weighted. Emissions during steady-state testing are to be reported mode-by-mode as well as in the final weighted form. Torque curves will be provided electronically for each engine map. Brake-specific fuel consumption (BSFC) will be measured during each engine map and provided with the map.

5.2.3.3 Fuel conditioning. When switching fuels, a conditioning cycle will be run to purge old fuel and stabilize engine operation on the new fuel. The conditioning cycle must represent normal engine operation and will be specified in the test/QA plan. The engine must be mapped prior to performing a test sequence each time a new test fuel (base fuel or candidate fuel) is used. Engine mapping is conducted following conditioning. The most recently generated engine map on base fuel shall be used in transient testing. The supplemental emissions test (SET) will be performed with the most recently conducted map.

5.2.3.4 ETV test procedures. For on-highway engines, the FTP is described at 40 CFR Part 86. The minimum immediate effects FM emission reduction ETV on-highway engine test at a single test point consists of one cold start FTP test, three hot start FTP tests, and one SET. The weighted cold start results shall be applied to each of the weighted hot start results to provide three (3) transient sets of data for each regulated pollutant and BSFC. Additional testing at each test point may be required to detect the expected emissions reduction, as described in Section 5.1.2.

US EPA ARCHIVE DOCUMENT

The SET for on-highway engines is specified at 40 CFR 86.1360. The SET is a 13-mode steady-state test cycle. The test sequence shall consist of using the FTP to perform one cold start and three hot start transient tests followed by one SET.

For nonroad engines, the FTP is described at 40 CFR Part 89. In most cases, nonroad engines will be verified with both the applicable steady-state cycle and the nonroad transient cycle. However, constant speed engines, such as for generators, may be tested using only the steady-state cycles. For nonroad engines, the basic minimum immediate emission reduction ETV test requires triplicate multimode FTP tests plus the diesel nonroad transient cycle. Additional testing at each test point may be required to detect the expected emissions reduction, as described in Section 5.1.2.

For locomotive engines, the FTP is described at 40 CFR Part 92. The marine engine FTP is described in 40 CFR Part 94. Additional testing at each test point may be required to detect the expected emissions reduction, as described in Section 5.1.2.

Future revisions to the applicable FTP or new procedures adopted in applicable regulations are incorporated in this protocol. Unless otherwise described in this document or identified in the approved test/QA plan, the FTP is to be followed in its entirety. In accordance with this protocol, any deviations from the test/QA plan will be noted and throughly documented by the testing organization in its report.

Requests for the use of alternate or special test procedures to better predict emissions and/or engine operation will not be rejected without consideration. All data quality and QA requirements of this protocol must be met by any alternate test, and this protocol relies on the QA incorporated in the FTP. Significant modification of the FTP sampling and analysis system is unlikely to be acceptable. Changes in the FTP that amount to re-arrangement of existing portions of the test procedure and retain the existing QA steps are more likely to be acceptable.

With these constraints, alternate or special test procedures may be proposed in the application for the technology and will be reviewed with the APCTVC for conformance to this generic protocol before test/QA plan preparation.

Existing data of any kind and chassis and in-use field (e.g., on-road testing devices) data are not acceptable as the basis for ETV.

5.2.4 ETV of Diesel FMs Delivering Immediate Emission Reductions

5.2.4.1 ETV testing sequence. Emission testing on the base fuel must be conducted first. For an arbitrary engine choice for which no historical emissions performance information is available, the base/candidate test points may be conducted in either sequence of base/candidate/base/candidate (BCBC), or base/candidate/ candidate/ base (BCCB). Each test point (B or C) is to include the same number of tests. For the special case of an engine having a substantial documented emissions history (explained further below), a test sequence of BBCC is permitted.

Table 4 outlines the minimum single highway diesel engine test for an immediate emissions reduction FM using the BCCB sequence. The minimum number of tests required at each point in the test sequence is given in Equation B-3. For example purposes, the FM being evaluated in Table 4 is assumed to be one whose expected emissions reduction is large enough that the minimum test set (one cold test, three hot starts, and one SET) at each test point provides a sufficiently narrow confidence interval. Other diesel engine applications would run the appropriate FTP test sequence.

US EPA ARCHIVE DOCUMENT

After the base fuel is used to conduct the prescribed minimum number of tests for the expected emission reduction, candidate fuel testing should be performed. After conducting the minimum number of prescribed tests on the candidate fuel, emission results for each pollutant should be analyzed. If the emission reduction achieved is less than expected, the applicant may run additional tests to support fuel performance. If additional testing on the candidate fuel is desired by the applicant, all testing on the candidate fuel should be completed before switching fuels.

Diesel engines are not expected to exhibit emissions deterioration such as is shown in Figure 1. However, for an unknown FM in an arbitrary engine, it is possible. Potential drift by the test diesel engine (Table 4, Step 11) is to be evaluated as follows:

1. By comparing base fuel emissions at the beginning and end of the test program. Initial and final base fuel results that are not statistically different indicate no deterioration and a zero slope emissions line.
2. By choosing an engine with a documented test history for which at least two baseline emissions measurements show constant emissions over a period that exceeds the expected total ETV test duration. The FM application should propose the engine and provide the requisite evidence of constant emissions so that the test/QA plan can be properly prepared. If the initial ETV baseline emissions result (Table 4, Step 3) is not statistically different from the previous two measurements for the engine, the final baseline test (Table 4, Step 10) may be conducted, on a separate day, prior to use of the FM, and the average emissions of the two will serve as the base-fuel emissions. That is, Step 10 becomes a new Step 3a.

Table 4. Minimum ETV Test Program for Single On-highway Diesel Engine and Immediate Effect FM

1.	Select representative engine and stabilize operation on base fuel.
2.	Map engine on base fuel and practice cycles.
3.	Conduct cold start, three hot starts, and SET on base-fueled engine with base fuel map.
4.	Switch to candidate FM, purge base fuel, and operate and stabilize engine.
5.	Map engine with FM. Practice cycles using base fuel map.
6.	Conduct cold start, three hot starts (using base fuel map), and SET (with FM map) on FM-fueled engine.
7.	Repeat cold start, three hot starts (using base fuel map), and SET (with FM map) on FM-fueled engine.
8.	Switch back to base fuel, purge FM fuel, and operate and stabilize engine.
9.	Perform second map using base fuel. Perform practice cycles using new base map.
10.	Using new base fuel map, conduct cold start, three hot starts, and SET.
11.	Compare initial and final base fuel emissions results for statistical differences.

5.2.4.2 Data reduction for immediate effects diesel FM. For highway diesel engines, emissions tests results are recorded at each test point for HC, CO, NO_X, PM and the other measured pollutants. For each pollutant, the single cold start emissions measurement (e_C) is combined with each of up to three hot start emission measurements (e_H) to obtain up to three composite emissions rates [$(E_{COMP})_m$] following the normal fractional calculation for highway engines:

$$(E_{comp})_m = \frac{(1/7)(e_c) + (6/7)(e_H)_m}{(1/7)(W_c) + (6/7)(W_H)_m} \quad (7)$$

where:

US EPA ARCHIVE DOCUMENT

(E_{COMP}) = weighted mass emission level in grams per brake horsepower-hour and, if appropriate, the weighted mass total hydrocarbon equivalent, in grams per brake horsepower-hour,

m = hot start test 1, 2, or 3,

e_c = mass emission level in grams or grams carbon mass equivalent, measured during the cold start test,

e_H = mass emission level in grams or grams carbon mass equivalent, measured during the hot start test,

W_C = total brake horsepower-hour (brake horsepower integrated over time) for the cold start test,

W_H = total brake horsepower-hour (brake horsepower integrated over time) for the hot start test.

Hot start tests that are combined with a cold start test must be obtained sequentially following that cold start, and no more than three hot starts may be combined with a single cold start or single SET. The composited FTP highway transient emission for each pollutant, E_{COMP}, is combined with a single SET as follows to obtain the combined tests emission rate (E) for each pollutant for each of the n tests at the test point:

$$(E)_i = 0.85 \bullet (E_{COMP})_i + 0.15 \bullet E_{SET} \quad (8)$$

for i = 1 to n tests required at each test point.

As an example, suppose a total of five $(E)_k$ measurements were required to be calculated at each test point to provide enough data. As stated by Equation 8, $(E_{COMP})_1$, $(E_{COMP})_2$ and $(E_{COMP})_3$ would be computed from the first cold start and the first three valid hot starts following the cold start. $(E_{COMP})_4$ and $(E_{COMP})_5$ would be computed from the second cold start and next two valid hot starts, giving the required total of five E_{COMP} values. One SET would be required for the first three E_{COMP} values and a second SET for the last two E_{COMP} values. Then the SET results would be combined with the E_{COMP} values to obtain five E_T values according to Equation 9. (The APCTVC recognizes that the emissions results generated in this way are not fully independent. This approach is a compromise allowed to reduce cost.)

The same process would be applied to both the base case and the candidate FM case.

The same general approach is applied to nonroad engines. Instead of combining a cold and hot start test result, E_{COMP} for nonroad tests is obtained from the nonroad multimode test following the weightings in Appendix B to Subpart E of 40 CFR Part 89 as appropriate for the intended nonroad use as shown in Equation 10.

$$(E_{COMP})_i = \sum_{j=1}^{k} f_j \bullet E_j \quad (9)$$

where:

$(E_{COMP})_i$ = combined emissions rate for test i of n tests required at test point,

k = total number of modes for intended application per 40 CFR 89,

f_j = mode weighting factor from 40 CFR 89, Subpart E, Appendix B, for j = 1,2, …, k modes,

E_j = pollutant emissions rate for j=1,2,..., k modes.

US EPA ARCHIVE DOCUMENT

The nonroad transient test cycle takes the place of the SET for nonroad applications. Only a single nonroad transient test is required at each test point. The nonroad transient cycle emissions are combined with the combined multimode test emissions as follows:

$$E_i = \boldsymbol{X} \bullet (E_{COMP})_i + \boldsymbol{Y} \bullet E_{NTTC} \text{ for } i = 1 \text{ to } n \text{ tests required at each test point} \quad (10)$$

where: $\boldsymbol{X}$ = constant determined by EPA-OTAQ,
$\boldsymbol{Y}$ = constant determined by EPA-OTAQ,
E_{NTTC} = emissions from nonroad transient test cycle.

The emissions reductions for both highway and nonroad engines are then calculated using Equations 1 through 6 from Section 5.1.3.1.

5.2.5 FMs Delivering Cumulative Emission Reductions

5.2.5.1 ETV of single diesel engine tests of cumulative effect FMs. The general procedure discussed in Section 5.1.3.4 is applied for single engine tests.

5.3 ETV of Gasoline FMs

This section applies to fuels and fuel additives used in spark-ignition engines.

5.3.1 Base Fuels

The general requirement for a base gasoline fuel within ETV is that it be widely and consistently available within the region where the FM will be marketed and defined narrowly enough to give consistent test results. As part of the ETV test, the base fuel will be analyzed and the result reported in the ETV report and verification statement. The applicant will specify the desired base fuel in his application, with his choice based on the intended market.

5.3.2 Test Vehicles

5.3.2.1 General requirements. The gasoline FM applicant may select as the target of the verification results a specific engine family. The APCTVC specifies the general requirements for vehicles that will be used in the test and provides the single engine test protocol. General ETV requirements for gasoline test vehicles are as follows:

1. Test vehicles must be in their certified condition, have no obvious signs of tampering, and be in reasonably good repair. Vehicles may have no new emission control components.
2. Whether for single or multiple vehicle verification, the test/QA plan must specify the vehicle selection criteria and procurement method. Test vehicles must have at least 10,000 miles on their engines, be in good working condition, and not have been screened for sensitivity to the candidate FM.
3. All prior maintenance and repair information must be documented.
4. Rebuilt engines are not allowed.
5. Vehicles must not exceed 110% of the applicable emissions certification standard during baseline testing. Exceeding any emissions standard must be the result of the normal distribution of emissions; that is, the vehicle and emission control system must be operating properly, with no obvious reason for the non-compliance.

US EPA ARCHIVE DOCUMENT

5.3.2.2 Number of test vehicles. For single LDV family verification, the specific LDV is the applicant's choice. The application for the FM should state the desired vehicle, and the characteristics of that vehicle will be included in the test/QA plan. If eventually seeking full U.S. fleet verification, the applicant is required to coordinate with EPA-OTAQ.

5.3.2.3 Nonroad use gasoline engines for FM verification. Gasoline FMs may be verified for emissions reductions in nonroad gasoline engines. The applicant recommends the desired test engine, which must meet the general criteria in Section 5.3.2.1.

5.3.3 General Test Procedures

All equipment used in the ETV testing must be maintained and operated in accordance with applicable FTPs. Raw test results are to be retained by the testing organization in the electronic format required for certification tests and made available to the APCTVC if requested. Results for each test phase are to be reported separately as well as with final weighted FTP test results.

5.3.3.1 Vehicle preparation and maintenance. Prior to baseline testing, test vehicles must have normal maintenance performed such as oil and air filter changes. Other recommended maintenance, such as positive crankcase ventilation (PCV), spark plugs, crankcase filter, etc., shall be performed if the normally recommended interval is due or would become due during the test program. Vehicles will be checked for trouble codes and maintenance indicator lights (MILs) and repairs performed before beginning the ETV test. No trouble codes may be stored when beginning ETV testing. Trouble codes set during testing must be recorded and described in the test records.

To the extent practical, the engine and test conditions should be maintained the same between the base and candidate FM tests. This consideration applies to all aspects of engine operation and maintenance. Routine engine maintenance must be performed before beginning a verification test and, once testing has started, routine engine maintenance is generally not allowed. If use of an FM requires that an engine be tuned for the FM, this requirement must be detailed in the test/QA plan and will be included in the report as a requirement for use of the FM. Resumption of testing following engine or test stand breakdown and repair will be evaluated by the APCTVC on a case-by-case basis and will be allowable only for brief shutdowns for which no emissions impact is considered likely. A full fuel analysis is required on both base and candidate FM fuel.

Before initiating ETV testing, the fuel tank(s) shall be drained, base fuel added to the 40% full level, and a triple preparation (three 505-second hot-start tests per the EPA Dynamometer Procedure 40 CFR 86.135-90) performed.

5.3.3.2 Required test procedures. For on-road vehicles and engines, the FTP is described by 40 CFR Part 86. For nonroad engines, the FTP is described by 40 CFR Part 90. The FTP applicable at the time of the test is to be used. Whenever an FTP test is performed on a light duty vehicle or light duty truck, it will be followed by a US06 test (40 CFR 86.159-00). Heavy duty gasoline engines are tested on an engine dynamometer (40 CFR 86 Subpart N).

The highway fuel economy test, cold CO test, and evaporative emission testing will be required of any FM that may reasonably be expected to affect fuel volatility. When evaporative emission testing is not being performed, the heat build portion of the test will not be required after adding fuel.

Requests by applicants to use alternate or special gasoline vehicle or engine test procedures to better predict emissions and/or engine operation in use will not be rejected without consideration. They must

US EPA ARCHIVE DOCUMENT

be proposed in the application and will be discussed before preparing the test/QA plan, which must incorporate a complete description of the ETV test. The ETV testing data quality and QA requirements of this protocol must be met by any alternate test. Significant modification of the FTP sampling and analysis system is unlikely to be acceptable. Alternate test procedures that amount to rearrangements of existing portions of the FTP test for which the existing test descriptions and QA procedures remain valid are more likely to be acceptable. Specific modes of operation may be required to assess emission reductions for particular in-use operating conditions. Existing data may be used for test design.

5.3.4 Gasoline FMs Delivering Immediate Emission Effects

A single gasoline LDV test point consists of a complete composite FTP test (cold start test plus a valid hot start test) and the US06 test. In accordance with 40 CFR 86.137-94, emissions from the gasoline FTP tests are measured and recorded for all pollutants (HC, CO, NO_X, PM) for both phases of the cold start (transient and stabilized) and for the transient phase of the hot start. A minimum of three test points is required for both the base fuel and the candidate FM. After the base fuel is used to conduct the prescribed minimum number of tests for the expected emission reduction, candidate fuel testing should be performed. After conducting the minimum number of prescribed tests on the candidate fuel, emission results for each pollutant should be analyzed. If the emission reduction achieved is less than expected, the applicant may run additional tests to support better FM performance. If additional testing on the candidate fuel is desired by the applicant, all testing on the candidate fuel should be completed before switching fuels.

Additional testing may be conducted if the minimum testing requirements do not demonstrate the targeted emission reductions by continuing to test with the candidate fuel and then performing a corresponding number of tests with the base fuel.

The weighted FTP mass emission rate E_{comp} for each pollutant is obtained as described in 40 CFR 86.144-94 as the sum of 43% of the cold start emissions per mile (E_C) and 57% of the hot start emissions per mile (E_H).

$$E_{comp} = 0.43 \bullet E_C + 0.57 \bullet E_H \quad (11)$$

The combined emissions for each pollutant from a single test, E, are computed as follows:

$$E = 0.72 \bullet E_{comp} + 0.28 \bullet E_{US06} \quad (12)$$

where: E_{US06} = emission rate for the US06 test.

Each value of E_T is computed from separate FTP and US06 measurements. Therefore, if three tests are required to have sufficient data at a test point, a total of three full FTP tests and three US06 tests are required.

Calculation of the single engine emissions reduction is completed using Equations 1 through 6, with the combined emissions for each pollutant, E, for the base case being substituted for E_B, and E for the FM case being substituted for E_F.

The same general approach is applied to nonroad gasoline engines. Instead of combining a cold and hot start test result, E for nonroad tests is obtained from the multimode nonroad test following the weightings in 40 CFR Part 90 as appropriate for the intended nonroad use as shown in Equation 16.

US EPA ARCHIVE DOCUMENT

$$E_i = \sum_{j=1}^{k} f_j \bullet E_j \qquad (13)$$

where:

E_i = emissions rate for test *i* of *n* tests required at each test point,
k = total number of modes for intended application per 40 CFR 90, for j = 1,2, …, k modes,
f_j = mode weighting factor from 40 CFR 90,
E_j = pollutant emissions rate for j=1,2,...k modes.

5.3.5 ETV of Gasoline Cumulative Effect FMs

5.3.5.1 ETV of single gasoline vehicle with cumulative effect FMs. The general procedure discussed in Section 5.1.3.4 is applied for single engine tests.

5.3.5.2 ETV of multiple gasoline vehicles with cumulative effect FMs. For fleet-wide emissions reductions, the emissions reduction for each pollutant is computed from a linear regression on the data from the tested vehicles (as for diesel engines) as described in Appendix D.

5.4 ETV of Lubricant FMs

This protocol was developed to verify the performance of lubricant FMs that are straightforward replacements of conventional crankcase lubricants. Lubricant FMs tested are expected to provide equivalent or better performance than those recommended by the original equipment manufacturer (OEM) for the test engine(s). By providing emissions control and unchanged maintenance requirements, these FMs may provide a net emission reduction.

If a candidate lubricant is not a straightforward replacement for conventional crankcase lubricants or cannot meet the performance specifications required by the OEM, the applicant must provide an appropriate means to demonstrate that any emission reductions identified will be achieved in-use. For example, if the FM candidate lubricant cannot maintain the oil change interval recommended by the OEM, the applicant must provide a compliance and enforcement plan that will verify that the new interval will be followed in use to assure projected emission reductions are achieved in use. This plan will then be considered an integral part of the technology and the verification will be for the lubricant and its written plan for use.

If a candidate lubricant requires a special oil filter or other companion technology to function, the application must specify the requirement. The test will then be designed for both the FM lubricant and the companion technology, and the ETV verification will be for both technologies as a system.

As with the other FMs, verification of emissions reductions for lubricants is based on comparison of emissions during a base case test with those during a test using the candidate lubricant. For the base case and candidate lubricant test, the duration is approximately one oil change cycle, with emissions tests conducted periodically during that cycle. Tests done under this protocol do not evaluate the long term engine and emission control system deterioration/improvement from candidate lubricants; the applicant should be confident of and have conducted adequate tests to confirm the long term effects of the lubricant.

US EPA ARCHIVE DOCUMENT

The applicant is responsible for providing necessary information on candidate and base lubricants as well as OEM specifications for lubricants and their change intervals for each test engine. All applicable specifications and ratings must be fully referenced and documented by the applicant. All additives contained in the candidate lubricant must be fully described. Any exceptions to the applicable specifications must be noted for discussion with the APCTVC and/or EPA-OTAQ. Additionally, the application must describe the lubricant, its source, all additives, and provide information showing that the candidate lubricant does not contribute to increased engine or emission control system deterioration. Where procedures are not specified in this section, applicable procedures in the gasoline or diesel sections must be followed.

5.4.1 Candidate Lubricants

The suitability of candidate lubricants for the proposed application will be evaluated based on comparison of the candidate FM's properties to those of a base lubricant for the tests referenced in Table 5. The lubricant FM application must report results for the tests in Table 5 (or their latest revision) for all grades proposed for use in the ETV verification. This table suggests ranges of results for these tests. Because test procedures and property standards may change, the protocol will not require compliance with these ranges. Instead, a verification will indicate how a candidate lubricant compares with an expected performance standard. All additives in the candidate lubricant must be fully described. This includes measurements of all properties listed in Table 5. The presence of additives or of performance specifications related to emission control system deterioration (such as phosphorus) will be specifically noted in the verification report because these could cause decreased emission control system durability or a reduced emission benefit after long term use.

US EPA ARCHIVE DOCUMENT

Table 5. FM Lubricant Properties and Tests[a]

Test	ASTM Number	Description	Range of Result
Kinematic viscosity @ 100 °C	ASTM D 445	Measures flow resistance of fluid to gravity	3.5 (SAE 0W) to 16.5 cSt (SAE 50)
Pour point	ASTM D 97	Measures temperature at which fluid sample will no longer flow by gravity	-25 to - 45 °C
Noack volatility	ASTM D 5800	Measures evaporation of fluid at 250 °C for 1 hr	0 to 30%
Flash point	ASTM D 92 or D 93	Temperature at which a spark will ignite a flame in the vapor space over test fluid	120 °C minimum
Rotating bomb oxidation test (RBOT)	ASTM D 2272	Measures time for uptake of 100 psi oxygen gas (by pressure drop) of fluid at 100 °C in closed, rotating vessel	30 minutes minimum
Chemical analysis	ICP Spectra or XRF	Quantitative analysis of elements	No halogens, Pb, catalyst poisons
Phosphorus content	ICP Spectra or XRF	Quantitative analysis of elements	1500 ppm maximum
Copper corrosion	ASTM D 130	Grades color change of copper surface after immersion in fluid for 3 hr at 100 °C	1B maximum
Rust prevention	ASTM D 665 A&B	Counts size and number of rust spots on fluid-treated steel surface in fresh water (A) and sea water (B)	Pass A
Foam control	ASTM D 892 Sequence I-IV	Measures foam head on fluid into which air is sparged under various conditions (Sequence I-IV)	None after 10 minutes in all sequences
Four ball wear	ASTM D 4172	Measures diameter of spot worn on stationary ball bearings by a driven ball bearing under 20 kg load	0.5 mm maximum
Falex pin and vee block	ASTM D 3233	Measures friction and wear on a pin spinning between blocks under measured clamping load	Steady state coeff. of friction = 0.15 max

[a] Society of Automotive Engineers (SAE) Document J300, Viscosity Grades for Engine Oils, December, 1999.

The applicant must provide a single mixed batch of the candidate lubricant FM(s) in sufficient quantity for the entire program. The ETV report will list the lubricant grades tested and the emissions reduction obtained.

5.4.2 Base Lubricant and Test Fuel

The applicant must recommend potential base lubricating oils for the ETV verification. They are to be widely distributed, conventional technology lubricants, and are expected to be petroleum- based. The base lubricant must meet the most recent performance specifications for each engine or vehicle model. Where OEM specifications have been superseded by a new grade, the new grade must be used as the base lubricant. From the recommended list, the APCTVC will choose one brand of base lubricant for all ETVs, and the verification report will note emission reductions relative to that base lubricant.

If the applicant knows that the candidate lubricant may be affected by fuel properties, this should be described in the application, will be factored into the test design, and will be reported as characteristic of

US EPA ARCHIVE DOCUMENT

the FM. As described in more detail below, the ETV test includes periodic emissions test sequences separated by mileage (time) accumulation periods. Test fuels meeting the base fuel specifications in the gasoline or diesel sections must be used at each test sequence of the program. Commercial fuel may be used for mileage accumulation, provided it is used consistently throughout the entire test. The test/QA plan will identify specific fuel properties for all phases of the program, and the ETV will report the measured emissions reduction specifically for the gasoline or diesel fuel used during the test.

The base lubricant and the test fuel must be obtained and prepared as needed such that both are available in sufficient quantities for the entire program.

5.4.3 Highway Use Test Engines or Vehicles

Test vehicle(s) or engine(s) used in the lubricant FM tests must be stable as described in the applicable gasoline and diesel FM sections. The base and candidate lubricants must meet the lubricant specifications for the test vehicle(s) or engine(s). Documentation of these specifications must be provided for each vehicle or engine.

5.4.3.1 Types of vehicles. The types of test vehicles shall be selected in accordance with the gasoline and/or diesel FM sections. Where more than one vehicle or engine will be tested, an effort should be made to maximize the diversity of engine characteristics, such as engine speed and operating temperatures, that might affect oil performance.

5.4.4 Nonroad Engine Selection

The general requirements for engine selection for ETV of modified fuels remains applicable for lubricant FMs intended for nonroad applications. The applicant may propose test engines in his application, and these recommendations will be reviewed by the APCTVC.

5.4.5 General Test Procedures

To minimize carryover effects between the lubricants, a purge of the test vehicle (engine) shall be performed each time the oil type is changed. If the base or candidate oil is clearly labeled with a specific purge step as standard operating procedure (SOP), that SOP will be incorporated in the test/QA plan. If a purge SOP is not provided, the test vehicle or engine must be operated for a full oil change interval on the new lubricant before the oil change interval during which emission testing will occur. This operation will help insure that a normal residual amount of used oil (base or FM lubricant) is in the test vehicle when testing is conducted. Whenever the oil is changed or added, the volume of all oil added or removed must be recorded. Prior to making any oil changes (removal or addition), the crankcase oil level and condition must be recorded.

5.4.5.1 Vehicle preparation and maintenance. All test vehicles/engines are to be in good operating condition and to have been maintained in accordance with OEM requirements. Vehicle information must be recorded and maintenance documented through shop records. Prior to beginning the ETV test sequence, the crankcase oil level and condition must be recorded. After the engine/vehicle start condition has been noted, normally scheduled maintenance that is due or may become due during the test program should be performed; and, if so equipped, spark plugs, PCV valve, and air and breather filters are to be changed. The condition of the parts removed is to be noted and these parts are to be retained. An oil sample may be obtained to determine oil condition. No MIL/OBD fault codes are to be present. This vehicle information must be reviewed for acceptability prior to beginning testing.

US EPA ARCHIVE DOCUMENT

Similarly, at the end of the testing program, spark plugs, PCV valve, and air and breather filters will be removed, retained, and their condition noted. The vehicle/engine will be inspected, and any MIL/OBD faults noted. The condition of the vehicle/engine, indications of oil deposits, leaking, or any other oil-related potential concerns will be noted and described in detail in the verification report.

For replacement lubricant FMs, the same brand and part number of oil filters (as specified by the vehicle or engine original equipment manufacturer) must be used throughout the program. The number of filters required for the entire ETV program must be procured prior to its beginning, and the oil filter used at any time randomly selected from that stock.

Base and candidate oils must each be batch-mixed to have enough for the entire program. All special mixing and/or handling procedures must be consistent with good engineering judgment and fully described in the test/QA plan. All storage, mixing, and/or handling instructions for the candidate oil must be fully described in the application.

5.4.5.2 Required test procedures. The required emission tests are described in the applicable gasoline and diesel FM test sections. Equipment and reporting requirements, are specified in the applicable federal regulations. If an oil analysis is performed on any oil from a test vehicle, the results of that analysis will be included in the verification report.

5.4.5.3 Service accumulation. The test/QA plan will specify a service accumulation schedule for each vehicle to follow over the oil change interval. The OEM oil change interval should be used unless a longer interval is needed to evaluate changes over a longer period of operation such as if the oil were not changed in time. An applicant may request a shorter oil change interval. Where more than one vehicle or engine will be tested, the service accumulation schedules for different vehicles should include severe and normal operation to confirm performance of the candidate oil over a broad range of operation. In all cases, the service accumulation on the base oil and candidate oil must be the same over the oil change interval.

5.4.6 Lubricant FM ETV Test Sequences

Figure 2 shows the form of lubricant FM effects that are contemplated in the GVP data analysis in its most complex form with both short-term and long-term deterioration. The same analysis applies in cases exhibiting no deterioration in either the short term (over a single oil change) or the long term, and with different slopes for the base and FM cases. The estimated log (emission reduction) is the difference between the base case and FM case emissions at the midpoint of the FM case service. The analysis is simplest when the test points are symmetrical as shown in Figure 2.

The ETV test for a single vehicle/engine consists of a purge with the new lubricant and alternating test sequences and mileage/hours accumulation periods. As implied in Figure 2, it is assumed within this protocol that the emissions effect will be measurable during the first oil change of the candidate oil (following the purge step). If cumulative effects are expected, additional mileage accumulation may be incorporated into the test/QA plan and steps taken to return the vehicle/engine to baseline operation as described in Section 5.1. The applicant will be expected to provide the mileage/hours required for the FM to reach full effectiveness and the time required to return the vehicle/engine to baseline operation.

US EPA ARCHIVE DOCUMENT

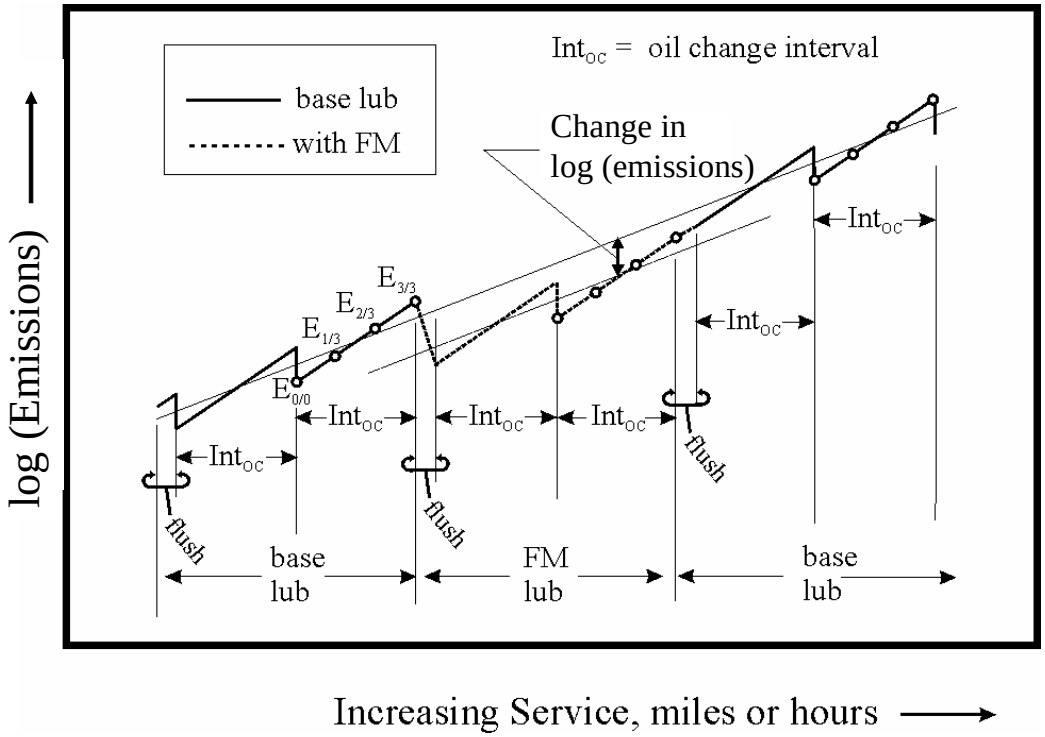

Figure 2. Lubricant FM Testing

The lubricant FM tests for light duty gasoline and all diesel engines are essentially the same as those described above for FMs. Figure 2 provides a graphic overview of the lubricant FM ETV test, and Table 6 gives the testing procedure for lubricant FMs. Details of the testing at the individual test points are as described in Sections 5.2 and 5.3 for diesel engines and gasoline vehicles, respectively.

Heavy Duty Engine Test Sequence
Map engine.
Practice FTP cycles.
Run cold start test.
Run up to three hot start tests without running another cold start.
Run the SET.
Weight and combine emissions results as described in Sections 5.2.4 and 5.2.5 to obtain the fully composited emission rate for each pollutant.

[a] Highway fuel economy testing is optional; but, if used, it must be performed after required tests and consistently in each test sequence to maintain test uniformity.

US EPA ARCHIVE DOCUMENT

5.4.7.1 Single engine test data analysis. If there is no indication of emission system deterioration (the means of the base case test are the same), the single engine data may be analyzed applying Equations 1 through 6 as described in Section 5.1.3.1. All eight base case tests should be averaged to generate the base case mean. The resulting emission reduction for each pollutant will be reported.

If comparison of the two base case test series shows a measurable increase in emissions, a least-squares line should be fitted to the data applying the principles given in Appendix E. For an experiment in with a symmetrical design (Figure 2), the mean emission reduction, $\hat{\Delta}$, is

$$\hat{\Delta}_j = \overline{E2_j} - \frac{\overline{E1_j} + \overline{E3_j}}{2} \tag{14}$$

where:

$\overline{E1}$ = the mean of the first four base case tests (in log-scale units) for the pollutant of interest,

$\overline{E2}$ = the mean of the four FM tests (in log-scale units) for the pollutant of interest,

$\overline{E3}$ = is the mean of the second four base case tests (in log-scale units) for the pollutant of interest.

Equation 18 is a recast version of Equation E-5 in Appendix E. As a percentage, the emission reduction is computed as

$$ER = (1 - e^{\hat{\Delta}_j}) \times 100\% \tag{15}$$

For non-symmetrical designs, the general form of the analysis in Appendix D will be applied.

5.4.7.2 Cumulative effect lubricant FM data analysis. The analysis of cumulative effect lubricant FM emission reductions is highly dependent on the type of cumulative effect caused by the FM. As of the date of this protocol, no data or theory were available describing the probable effect of cumulative effect FMs. As is shown in Appendix E, the effect of a lubricant FM is totally confounded with a long-term quadratic effect for a 12-test experimental design such as is shown in Figure 2. Therefore, more complex data analyses are not likely to bear fruit. In addition, no cumulative effect lubricant FM vendor has applied to ETV and no such effects have been postulated to the APCTVC. Therefore, all lubricant FM technologies will be treated as providing an immediate effect for the purposes of this protocol.

Should an applicant propose a cumulative effect lubricant, the APCTVC and the testing organization will develop a specific experimental design that applies the test design criteria stated or implied in this protocol for the other technologies.

6.0 REPORTING AND DOCUMENTATION

This section describes the procedures for reporting data in the verification report and verification statement. The specifics of what data must be included and the format in which the data must be included are addressed in this section (e.g., QA/QC summary forms, raw data collected, photographs/slides/video tapes). The verification report for each technology will include near the

US EPA ARCHIVE DOCUMENT

beginning a verification statement that summarizes the ETV results. An example draft is attached as Appendix A. The verification report, including the verification statement, will be written by the APCTVC based on the test report submitted by the testing organization. The verification report and verification statement will be reviewed by the APCTVC and the technology applicant before being submitted to EPA for review and approval as specified in the ETV QMP.

6.1 Reports

Based on the test report from the laboratory, the APCTVC will prepare the draft verification report, which includes the following topics:

1. Verification statement;
2. Introduction;
3. Description and identification of product tested;
4. Procedures and methods used in testing;
5. Statement of operating range over which the test was conducted;
6. Summary and discussion of results as required to
    a. support the verification statement,
    b. explain and document necessary deviations from the test plan, and
    c. discuss QA issues;
7. References; and
8. Appendices:
    a. QA/QC activities and results,
    b. Raw test data, and
    c. Equipment calibration results.

The verification statement will include the following:

9. Technology applicant's name and technology's descriptive information,
10. Summary of ETV test program,
11. Results of the ETV test,
12. Notice of control device warranty and any limitations of the ETV results, and
13. Brief QA statement.

Review and approval of the draft ETV report and statement are described in Section 3.0.

6.2 Data Reduction

Data from measurements made as part of the ETV test will be reported as emissions rates in grams/kilowatt-hour (g/kW-h) (grams/brake horsepower-hour [g/bhp-hr]) or grams/mile (g/mi) and as percentage emission reductions from the baseline engine. The confidence limits will be presented as well as the mean emissions reduction, as discussed in Section 5.1.2. When they would be helpful to the mobile sources community because of established usage, the appropriate English engineering units will be supplied parenthetically.

7.0 DISSEMINATION OF ETV REPORTS AND STATEMENTS

After an FM technology has been tested and the draft verification report and verification statement prepared by the APCTVC, the APCTVC will send a draft of both to the applicant for review prior to

US EPA ARCHIVE DOCUMENT

submission to EPA and release of the approved report to the public. This gives the applicant the opportunity to review the results, test methodology, and report terminology while the drafts remain working documents and are not publicly accessible. The applicant may submit comments and revisions on the draft statement and report to the APCTVC. The APCTVC will consider these comments and may suggest revisions of its own.

After incorporating appropriate revisions, the draft final verification report and verification statement will be submitted to EPA for review and approval. A signed original verification statement within the verification report will be filed and retained by the APCTVC, and signed originals will also be provided in verification reports to the applicant and to EPA. Three additional paper copies of the ETV report will be provided to the applicant. Further distribution of the ETV report, if desired, is at the applicant's discretion and responsibility. However, approved verification statements and verification reports will be posted on the ETV Web site for public access without restriction. The verification report report appendices will not be posted on the Web site, but will be publicly available from the APCTVC.

8.0 APPLICANT'S OPTIONS SHOULD A TECHNOLOGY PERFORM BELOW EXPECTATIONS

ETV is not a technology research and development program; technologies submitted to ETV are to be commercially ready and with well-understood performance. Tests that meet the ETV data quality requirements (a valid FTP test) are considered valid and suitable for publishing; however, a technology may fail to meet the applicant's expectations. Based on limited testing, for instance, the applicant might expect an emission reduction of 30% ± 7% result. However, the actual ETV result from the more complex FTP test cycle might be 20% ± 15%. The APCTVC will use its experience to avoid this situation, but it is possible. In this case, the applicant may choose to schedule additional tests, may accept the result and complete the verification, or may request that a verification statement not be issued. However, ETV reports are always in the public domain and will be posted on the ETV Web site. Verification reports will be written and will be available from EPA for review by the public regardless of a request not to issue a verification statement.

As another example, an applicant might expect a mean of 10% reduction with a confidence interval of ±5%, but testing results in an actual verification shows a mean reduction of 5% with a confidence interval of ±7% reduction. In this case, the ETV data are insufficient to verify that the technology provided any reduction at all. Additional tests must be scheduled and a statistically significant reduction obtained for a verification statement to be issued. Inability to detect a statistically significant emission reduction (or failure to have sufficient tests) will prevent completion of the ETV, and the results of the ETV will be reported publicly stating that performance could not be distinguished from 0% reduction. A verification statement will not be issued in this case.

In either of the above cases, the applicant may improve the product and resubmit it under a new model identification for ETV testing. ETV reports and statements for acceptable tests of the new product will be issued as they are processed by the APCTVC and EPA (except that the results for several identical tests performed in rapid succession will be released simultaneously).

9.0 LIMITATIONS ON TESTING AND REPORTING

To avoid having multiple ETV reports for the same product and to maintain the ETV testing as a cooperative effort with the applicant, the following restrictions apply to ETV testing under this protocol:

US EPA ARCHIVE DOCUMENT

- Applicants may submit only products they manufacture or whose distribution they control. Applicants may not submit for ETV testing control systems whose use is not in their control except with the agreement of the manufacturer or vendor.
- For a given product (e.g., brand and model), APCTVC policy is that only one ETV report and statement will be issued for any single application.
- Air pollution control technology frequently performs differently in different applications. Applicants may request additional tests of essentially identical technology if it is being applied to pollution sources that are clearly different from those for which verifications have been obtained.

10.0 REQUIREMENTS FOR TEST/QA PLAN

10.1 Quality Management

All testing organizations participating in this ETV Program must meet the QA/QC requirements defined below and have an adequate quality system to manage the quality of work performed. Documentation and records management must be performed according to the ETV QMP (U.S. EPA, 2002a) or its superceding document. Testing organizations must also perform assessments and allow audits by the APCTVC (headed by the APCT QA Officer) and EPA corresponding to those in Section 11.

All testing organizations participating in the Retrofit Air Pollution Control Technologies for Highway and Nonroad Use Diesel Engines Program must have an ISO 9000-accredited (ISO, 1994) or ANSI E4-compliant (ANSI, 1994) quality system and an EPA- or APCTVC-approved QMP.

10.2 Quality Assurance

All ETV testing will be done following an approved test/QA plan that meets *EPA Requirements for Quality Assurance Project Plans* (U.S. EPA, 2001c) and Part B, Section 2.2.2 of EPA's ETV QMP (U.S. EPA, 2002a). These documents establish the requirements for test/QA plans and the common guidance document, *Guidance for Quality Assurance Project Plans* (U.S. EPA, 2002b), provides guidance on how to meet these requirements. The APCT Quality Management Plan (RTI, 1998) implements this guidance for the APCTVC.

ETVs conducted under this generic protocol utilize test procedures described in the FTP (40 CFR Part 86 for highway engines and 40 CFR Part 89 for nonroad engines). The test/QA plan must describe in adequate detail how the FTP test methods are implemented by the testing organization. Replication of the FTP text is neither expected nor desired. The test/QA plan should reference the FTP in detail, by section and subsection, as appropriate for the topic under consideration. Any deviations from the FTP must be identified and explained. Internal SOPs may be referenced provided they are available for audit review. (SOPs need not be incorporated into the test/QA plan except by reference. If considered proprietary to the testing organization, they should be clearly marked.) When the FTP offers alternative test procedures or equipment, the test/QA plan must identify the alternative implemented. Similarly, if a range of operating parameters is allowed by the FTP, the specifics of the particular implementation must be provided. For a testing organization with multiple test cells, these details may be tabulated and incorporated by attaching a table and identifying the test cell on the test report. Steps the testing organization will take to ensure acceptable data quality in the test results are also identified in the test/QA plan. Detailed reference to SOPs, the calibration portions of the FTP, or other available documents is encouraged. Any needed SOPs will be developed in accordance with *Guidance for Preparing Standard Operating Procedures (SOPs)* (U.S. EPA, 2001b.)

US EPA ARCHIVE DOCUMENT

The testing organization must prepare a test/QA plan and submit it for approval by the APCTVC. The test/QA plan must also be approved by EPA before the testing organization can begin ETV testing.

A test/QA plan contains the 24 elements listed below, the contents of which may be stand-alone or include references to the FTP or other widely distributed and publicly available sources. Legible hand-notated diagrams from the FTP are acceptable. If specific elements are not included, an explanation for not including them must be provided.

Group A Elements: Project Management

A1 Title and Approval Sheet
A2 Table of Contents
A3 Distribution List
A4 Project/Task Organization
A5 Problem Definition/Background
A6 Project/Task Description
A7 Quality Objectives and Criteria
A8 Special Training/Certifications
A9 Documentation and Records

Group B Elements: Data Generation and Acquisition

B1 Sampling Process Design (Experimental Design)
B2 Sampling Methods
B3 Sample Handling and Custody
B4 Analytical Methods
B5 Quality Control
B6 Instrument/Equipment Testing, Inspection, and Maintenance
B7 Instrument/Equipment Calibration and Frequency
B8 Inspection/Acceptance of Supplies and Consumables
B9 Non-direct Measurements
B10 Data Management

Group C Elements: Assessment and Oversight

C1 Assessments and Response Actions
C2 Reports to Management

Group D Elements: Data Validation and Usability

D1 Data Review, Verification, and Validation
D2 Verification and Validation Methods
D3 Reconciliation with User Requirements

The APCTVC will provide a test/QA plan template that illustrates its expectations.

10.3 Additional Requirements To Be Included in Test/QA Plan

The test/QA plan must include or reference a diagram and description of the extractive gaseous measurement system to be used for the testing and a list of the reference analyzers and measurement ranges to be used for quantifying the concentrations of all gaseous compounds to be measured, including both primary and ancillary pollutants.

US EPA ARCHIVE DOCUMENT

The test/QA plan must include or reference a schematic drawing showing all sample and test locations, including the inlet and outlet to the technology sampling locations. The location of flow disturbances and the upstream and downstream distances from the sampling ports to those flow disturbances must be noted. The number of traverse points that will be sampled must be provided.

The test/QA plan must include or reference the appropriately detailed descriptions of all measuring devices that will be used during the test.

The test/QA plan must explain or reference the specific techniques to be used for monitoring process conditions appropriately for the source being tested. It must also note the techniques that will be used to estimate any other operational parameters.

The test/QA plan must include and document estimates of historical measurement variability that will be used, as discussed in Section 5.1.1 and Appendix B, to compute the number of tests required and provide confidence intervals on single-test ETVs.

The test/QA plan must include a list of data quality indicator goals for individual measurements that conform to those specified in the relevant sections of the FTP and the corresponding acceptance criteria.

11.0 ASSESSMENT AND RESPONSE

Each independent testing organization must conduct internal assessments of its quality and technical systems and must allow external assessments of these systems by APCTVC QA personnel and by EPA QA personnel. After an assessment, the testing organization will be responsible for developing and implementing corrective actions in response to the assessment's findings.

As appropriate, the APCTVC and/or EPA will conduct assessments to determine the testing organization's compliance with its test/QA plan. The requirement to conduct assessments is specified in EPA's ETV QMP (U.S. EPA, 2002a), and in RTI's APCTVC QMP (APCTVC, 1998). EPA will assess RTI's compliance with APCTVC's test/QA plans. APCTVC will assess the compliance of other organizations with their test/QA plans. The assessments will be conducted according to *Guidance on Technical Audits and Related Assessments for Environmental Data Operations* (U.S. EPA, 2000) and *Guidance on Assessing Quality Systems* (U.S. EPA, 2001a.)

11.1 Assessment Types

Quality system assessment—Qualitative assessment of a particular quality system to establish whether the prevailing quality management structure, policies, practices, and procedures meet EPA requirements and are adequate for ensuring that the type and quality of measurements needed are obtained.

Technical systems audit—Qualitative on-site audit of the physical setup of the test. The auditors determine the compliance of testing personnel with the test/QA plan.

Performance evaluation audit—Quantitative audit in which measurement data are independently obtained and compared with routinely obtained data to evaluate the accuracy (bias and precision) of a measurement system.

Audit of data quality—Qualitative and quantitative audit in which data and data handling are reviewed and data quality and data usability are assessed.

US EPA ARCHIVE DOCUMENT

11.2 Assessment Frequency

Activities performed during verifications performance operations that affect the quality of the data will be assessed regularly and the findings reported to management to ensure that the requirements stated in the generic verification protocols and the test/QA plans are being implemented as prescribed.

The types and minimum frequency of assessments for the ETV Program are listed in Part A Section 9.0 of EPA's ETV QMP (U.S. EPA, 2002a). Tests conducted by the APCTVC will have, at a minimum, the following types and numbers of assessments:

- Quality system audit: Self-assessments by the testing organization at least once, and at least one independent assessment of the testing organization.
- Technical systems audits: Self-assessments (qualitative) by the testing organization at least once per test, and at least one independent assessment of the testing organization.
- Performance evaluation audits: Self-assessments (quantitative) by the testing organization on each test, and at least one independent assessment of the testing organization.
- Audits of data quality: Self-assessments (quantitative and qualitative) by the testing laboratory of at least 10% of all the ETV data with detailed reports of the audit results to be included in the data packages sent to the APCTVC for review.

The independent assessments of tests conducted by RTI for the APCTVC will be performed by EPA. The independent assessments of other organizations will be performed by the APCTVC.

11.3 Response to Assessment

When needed, appropriate corrective actions shall be taken and their adequacy verified and documented in response to the findings of the assessments. Data found to have been taken from nonconforming technology shall be evaluated to determine its impact on the quality of the required data. The impact and the action taken shall be documented. Assessments are conducted according to procedures contained in the APCT QMP. Findings are provided in audit reports. Responses by the testing organization to adverse findings are required within 10 working days of receiving the audit report. Followup by the auditors and documentation of responses are required.

12.0 SAFETY MEASURES

12.1 Safety Responsibilities

The testing organization's project leader is responsible for ensuring compliance with all applicable occupational health and safety requirements. Each individual staff member is expected to follow the requirements and identify personnel who deviate from them and report such action to their supervisor.

12.2 Safety Program

The testing organization must maintain a comprehensive safety program and ensure that all test personnel are familiar with and follow it.

US EPA ARCHIVE DOCUMENT

APPENDIX A: EXAMPLE VERIFICATION STATEMENT

Appendix A is an example verification statement written for a generic fuel modification intended to reduce engine emissions from mobile diesel engines. The technology is assumed to have an immediate effect and to be directed at a highway use engine. It is assumed to provide sufficiently large emissions reductions, requiring only the minimum number of tests by the minimum-number-of-tests calculation.

This generic verification statement is intended only to show the form of a verification statement. It will require modification for each technology verified, depending on the details of that technology's design, construction, and operation. The test/QA plan written for each test will include a draft verification statement customized for the technology actually being tested. The text of that specific verification statement will address the significant parameters that apply to the technology tested.

The U.S. Environmental Protection Agency (EPA) has created the Environmental Technology Verification (ETV) Program to facilitate the deployment of innovative or improved environmental technologies through performance verification and dissemination of information. The goal of the ETV Program is to further environmental protection by accelerating the acceptance and use of improved and cost-effective technologies. ETV seeks to achieve this goal by providing high quality, peer reviewed data on technology performance to those involved in the design, distribution, financing, permitting, purchase, and use of environmental technologies.

ETV works in partnership with recognized standards and testing organizations; stakeholder groups which consist of buyers, vendor organizations, permitters, and other interested parties; and with the full participation of individual technology developers. The program evaluates the performance of innovative technologies by developing test plans that are responsive to the needs of stakeholders, conducting field or laboratory tests (as appropriate), collecting and analyzing data, and preparing peer-reviewed reports. All evaluations are conducted in accordance with rigorous quality assurance protocols to ensure that data of known and adequate quality are generated and that the results are defensible.

The Air Pollution Control Technology Verification Center (APCTVC), one of six centers under the ETV Program, is operated by RTI, in cooperation with EPA's National Risk Management Research Laboratory. The APCTVC has evaluated the performance of a _____*TYPE*_____ fuel modification for mobile diesel engines, the *TECHNOLOGY* by *COMPANY NAME*.

US EPA ARCHIVE DOCUMENT

ETV TEST DESCRIPTION

All tests were performed in accordance with the APCTVC ***Generic Verification Protocol for Determination of Emissions Reductions Obtained by Use of Alternative or Reformulated Liquid Fuels, Fuel Additives, Fuel Emulsions, and Lubricants for Highway and Nonroad Use Diesel Engines*** *and Light Duty Gasoline Engines* and the specific technology test plan "ETV Test/QA Plan for *TECHNOLOGY NAME*" These documents include requirements for quality management, quality assurance, procedures for product selection, auditing of the testing organizations, and test reporting format.

The mobile diesel engine air pollution control technology was tested at *TESTING ORGANIZATION*. The performance verified was the percentage emission reduction achieved by the fuel modification for particulate matter (PM), nitrogen oxides (NO_X), hydrocarbons (HCs), and carbon monoxide (CO) relative to the performance of the same engine on base fuel. Operating conditions were documented and ancillary performance measurements were also made. The basic modules of the test procedure are found in the Federal Test Procedures (FTPs) for emissions certification of diesel highway engines (40 CFR Part 86), diesel nonroad engines (40 CFR Part 89), and light-duty gasoline engines (40 CFR Part 86). Multiple replicate tests are required, depending on the type of fuel modification (FM) and the expected emissions reductions. A summary description of the ETV test is provided in Table A-1.

Table A-1. Summary of the Conditions for ETV Test of *TECHNOLOGY NAME* on ENGINE DESCRIPTION

Test conducted	Highway Transient Federal Test Procedure (FTP)
Engine family	*ENGINE MFGR NAME* Series *XXXYYY*, ??? operating hours prior to test
Engine size	YYY kW (XXX hp)
Technology	ACME Mark II Fuel Additive blended into CA 15 ppm ultra-low sulfur diesel fuel (ULSD)
Technology description	Additive is blended at the terminal with the base fuel at 0.02% by weight.
Test cycle or mode description	For both the base and FM-fueled tests, duplicate test sequences were run, each consisting of 1 cold start, 3 hot starts, and 1 highway steady-state (SET) cycle.
Base fuel description	EPA standard diesel per 40 CFR Part 86.1313-98
Critical measurements	PM, NO_X, HCs, and CO per the FTP
Ancillary measurements	CO_2, exhaust temperature, fuel consumption

VERIFIED TECHNOLOGY DESCRIPTION

This verification statement is applicable to the *TECHNOLOGY NAME* (to include model number and other identifying information as needed), which is a proprietary fuel additive manufactured by *MANUFACTURER NAME*. *TECHNOLOGY NAME* is distributed to fuel terminals and is blended into diesel fuel at the time all other additives are blended.

This verification statement describes the performance of *TECHNOLOGY NAME* on the diesel engine identified in Table A-1. The fuel additive, *TECHNOLOGY NAME*, is expected to provide similar emissions control performance on other engines having similar exhaust stream characteristics (similar fuel and engine technology) when properly sized for the application.

US EPA ARCHIVE DOCUMENT

VERIFICATION OF PERFORMANCE

TECHNOLOGY NAME achieved the emissions reduction shown in Table A-2 at the stated conditions. The number of required ETV tests required was estimated to be the minimum test, consisting of one cold start, three hot starts, and one SET for each of six baseline tests and two candidate FM tests. This estimate was confirmed by the ETV test results. For the purposes of determining the status of the technology in regard to EPA's voluntary retrofit program, the prospective user is encouraged to contact EPA-Office of Transportation and Air Quality (OTAQ) or visit the retrofit program web site at http://www.epa.gov/otaq/retrofit/.

Table A-2. Verified Emissions Reductions for *TECHNOLOGY NAME*

Test Engine: Manufacturer's Name and Model No. AA1	Technology Test			
			Emissions Reduction, %[a]	
	Base Fuel	Candidate FM	Raw[b]	Discounted[c]
Critical Measurements of Emissions				
Hot start PM, g/bkWh (g/bhp-hr)or g/mi				
Composited PM, g/bkWh (g/bhp-hr)				
Hot start NO_X, g/bkWh (g/bhp-hr)				
Composited NO_X, g/bkWh (g/bhp-hr)

[d](Candidate PM-base fuel)/Base fuel x 100.

The APCT QA Officer has reviewed the test results and quality control data and has concluded that the DQOs given in the generic verification protocol and test/QA plan have been attained.

During the ETV tests, EPA or APCTVC QA staff conducted technical assessments at the testing organization. These confirm that the ETV tests were conducted in accordance with the testing organization's EPA-approved test/QA plan.

This verification statement verifies the emissions characteristics of *TECHNOLOGY NAME* within the stated range of application. Extrapolation outside that range should be done with

US EPA ARCHIVE DOCUMENT

caution and an understanding of the scientific principles that control the performance of *TECHNOLOGY NAME*. This verification focused on emissions. Potential technology users may obtain performance information from the manufacturer.

In accordance with the generic verification protocol, this verification statement is valid commencing on *DATE* indefinitely for application of *TECHNOLOGY NAME* within the range of applicability of the statement.

APPENDIX B: DETERMINING MINIMUM NUMBER OF TESTS REQUIRED AT EACH TEST POINT

The ETV program for mobile source emissions requires that a testing program for a given technology attempt to achieve the following for each vehicle tested:

- The emissions reduction (ER) is to be tested using a t-test with significance level of 0.05; the null hypothesis is that the FM produces no reduction, and the alternative is that it reduces emissions.
- For the applicant's expected ER, a statistical power of 0.90 is desired.

For FM, the t-test can be formulated in terms of a confidence interval as in equation (4) of the protocol document, or as the ratio (observed ER)/(square root of variance of ER). The goal of this appendix is to derive the sample size needed for this statistical test to achieve the desired level of power.

An approximate variance expression for the emissions reduction is embedded in eq. (4) of the protocol document. This variance is

$$Var(ER) \approx \left(\frac{1}{\bar{E}_B}\right)^2 \left[\frac{s_F^2}{n_F} + (1-ER)^2 \frac{s_B^2}{n_B}\right] \qquad \text{(B-1)}$$

where $\bar{E}_B$ = the mean of the baseline emissions
s_F^2 = the variance of the FM emissions
s_B^2 = the variance of the baseline emissions
n_F = the number of emissions measurements in the FM sample
n_B = the number of emissions measurements in the baseline sample

To get an initial sample size, assume that

$$n = n_B = n_F \text{ and } s_B^2 = s_F^2 = s^2 .$$

Then (B-1) becomes

$$Var(ER) = \frac{1}{n}\frac{s^2}{E_B{}^2}\left[1 + (1-ER)^2\right] \qquad \text{(B-2)}$$

Let μ_B and μ_F denote the true mean emissions level for the given vehicle under baseline and FM conditions, respectively. Assume that we want to have a probability of 1-β of declaring significance if the FM results in an emissions level equal to $k\mu_B$, where, for instance, k might be 0.95. The true ER would then be given by $\frac{\mu_B - \mu_F}{\mu_B} = 1-k,$ or 0.05. Then, if we want n to be

large enough to detect an true ER of (1-k) with power (1-β), an approximate formula for n would be given by,

$$n \geq \frac{\left(z_{1-\alpha} + z_{1-\beta}\right)^2 \left(\sigma^2 / \mu_B^2\right)\left[1+k^2\right]}{(1-k)^2} + \frac{z_{1-\alpha}^2}{2} \qquad \text{(B-3)}$$

where μ_B = the true population mean baseline emissions rate

σ^2 = the true population measurement-error variance (for both baseline and fuel additive emissions)

$Z_{1-\alpha}$ = the standard normal deviate associated with probability 1-α

$Z_{1-\beta}$ = the standard normal deviate associated with probability 1-β.

The n calculated in (B-3) is the sample size for both FM and baseline tests (i.e., the total number of tests is 2n); the calculated n should be rounded up to next highest integer. The first term in (B-3) is based on a modification of the standard sample size formula for a one sided z-test; note that it depends on the magnitude of the effect to be detected (k), the relative measurement-error variance (in the parentheses), and the specified error rates (α and β). The second term is a correction factor that accounts for the fact that a t-test rather than z-test (i.e., normal-distribution-based test) is used, since n will generally be small. A derivation of the correction factor is available in Appendix A of the EPA G-4 guidance document (*Guidance on the Data Quality Objectives Process* (EPA/600/R-96/055)).

As an example of applying (B-3), assume the following:
α=0.05, so $z_{1-\alpha}$=1.645;
β=0.10 when k=0.95, so $z_{1-\beta}$=1.282;
relative measurement error standard deviation = 0.02 (i.e., 2%).

Then substituting into (B-3) yields

$$n \geq \frac{(1.645+1.282)^2 (0.02)^2 [1+(0.95)^2]}{(1-0.95)^2} + \frac{(1.645)^2}{2} = 2.61 + 1.35 = 3.96 \qquad \text{(B-4)}$$

In this situation, 4 baseline and 4 FM tests would be sufficient to demonstrate the emissions reduction with the desired confidence.

US EPA ARCHIVE DOCUMENT

APPENDIX C: USE OF LOG SCALE TO TEST EMISSIONS REDUCTIONS

Let 100δ represent the true percentage reduction in emissions due to a candidate FM relative to the baseline emissions. That is, if there were no measurement error and no temporal variation associated with measurements, then we would expect the baseline emissions, E_B, and the FM-based emissions, E_F, to be related as

$$\delta = \frac{E_B - E_F}{E_B} \quad . \tag{C-1}$$

This implies that

$$E_B \delta = E_B - E_F \tag{C-2}$$

or

$$E_F = E_B (1 - \delta) \, . \tag{C-3}$$

Now suppose there is a series of n measurements for each type emission (E_{Bi} and E_{Fi}, $i=1,2,...,n$) and that these are summed. Then, from Equation C-3, the sums would be expected to be related as

$$\sum_{i=1}^{n} E_{Fi} = \left(\sum_{i=1}^{n} E_{Bi} \right) (1 - \delta) \, . \tag{C-4}$$

This suggests that a natural estimator for (1-δ) would be the ratio of the sums, or equivalently, that an estimator $\hat{\delta}$ for δ is

$$\hat{\delta} = 1 - \frac{\sum_{i=1}^{n} E_{Fi}}{\sum_{i=1}^{n} E_{Bi}} \quad . \tag{C-5}$$

This is the estimator described in Equation 3 of Section 5.1.3.1 of this generic verification protocol. It was proposed for use in simple before-versus-after analyses in which no residual effects were anticipated. In that context, confidence intervals for δ were developed which were used for testing the null hypothesis, H_0: δ = 0, versus the alternative hypothesis, H_A: δ > 0.

Elsewhere in this generic verification protocol, the use of a log-scale for assessing emission reductions is advocated. In particular, in testing fuel additives and lubricants where carry-over effects may occur and where phase-in periods are needed, it is not practical to test the baseline and FM conditions at essentially the same mileage or hours of engine operation. A log-scale

US EPA ARCHIVE DOCUMENT

model is proposed for estimating baseline emissions at that point where the FM tests are conducted. This is appropriate for several reasons.

First, the log-scale analysis is much easier to deal with statistically. Defining an estimator of δ in a manner analogous to Equation C-5 would result in complex variance formulas and complex formulas for approximate degrees of freedom because, in the original scale, measurement error variances are likely to change with varying emission levels. Use of the log scale, which presumes that standard deviations of measured emissions are approximately proportional to their magnitude, allows the relevant variances to be calculated in a simple fashion and for degrees of freedom to be determined exactly.

Second, when measurement errors are relatively small (e.g., relative standard deviations [RSDs] less than 20%) and when effects to be detected are relatively small (e.g., 5% or 10%, rather than 50%), the log-scale analysis will produce results nearly identical to that implied by Equation C-5. To see this, the log-scale equivalents of the above relationships are defined. Note that Equation C-3 implies (all logs are natural logarithms)

$$\ln(E_F) = \ln(E_B) + \ln(1-\delta). \tag{C-6}$$

For a series of measurements, then

$$\ln(1-\delta) = \mu_F - \mu_B \quad , \tag{C-7}$$

where μ_F and μ_B are the true ln-scale mean emissions for FM and base respectively.

A natural estimator of ln(1-δ) is therefore the difference in the observed ln-scale means from a series of measurements:

$$\ln(1-\delta) \cong \overline{Y}_F - \overline{Y}_B, \tag{C-8}$$

where $\overline{Y}_F$ and $\overline{Y}_B$ are the observed log-scale means. This implies that the $\tilde{\delta}$ can be estimated in terms of the ratio of the geometric means (GMs):

$$\tilde{\delta} = 1 - \frac{\exp(\overline{Y}_F)}{\exp(\overline{Y}_B)} \equiv 1 - \frac{GM_F}{GM_B} \quad . \tag{C-9}$$

Note that the hypotheses expressed in Equation C-6 can be equivalently stated in log-scale units as

$$H_0: \ln(1-\delta) = 0 \text{ versus } H_A: \ln(1-\delta) < 0 \tag{C-10}$$

or

US EPA ARCHIVE DOCUMENT

$$H_0: \mu_F = \mu_B \text{ versus } H_A: \mu_F < \mu_B \,. \qquad \text{(C-11)}$$

The similarity of the results obtained via the alternate approaches for estimating, and testing for, emission reductions is demonstrated by the simulation results given in Table C-1. Three different sample sizes were considered. In each case, a log-scale measurement error standard deviation of 0.1 (essentially a 10% RSD) was used. The true effects shown in column 2 were used to generate normally distributed "data." The estimated values of the effects and the results of the respective t tests are very similar, especially for the smaller effect sizes.

Table C-1. Summary of Simulation Results

US EPA ARCHIVE DOCUMENT

APPENDIX D: DATA ANALYSIS FOR CUMULATIVE EFFECT FMs

Assume that a series of emission measurements are made at each of four mileage points as indicated in Figure 1 of this generic verification protocol. In particular, assume that the third mileage point is for the candidate FM and that the other three points represent baseline measurements. Let X denote the mileage and let Y denote the natural log of the emissions for a given contaminant. Let $\overline{X}_{Fj}$ and $\overline{X}_{Bj}$ denote the average mileages associated with the FM measurements and baseline measurements, respectively, for vehicle *j*. For a single vehicle, the FM effect, Δ_j, is defined as the difference in ln(emissions) occurring at $\overline{X}_{Fj}$. The value $\hat{\Delta}_j$, which is an approximation of Δ_j, can be estimated as

$$\hat{\Delta}_j = \hat{Y}_{Fj}(\overline{X}_{Fj}) - \hat{Y}_{Bj}(\overline{X}_{Fj}) \tag{D-1}$$

where $\hat{Y}_{Fj}(\overline{X}_{Fj})$ is the predicted FM-based emissions at the (average) mileage associated with those measurements, and $\hat{Y}_{Bj}(\overline{X}_{Fj})$ is the predicted baseline emissions at that same mileage. With the measurement design indicated above, $\hat{Y}_{Fj}(\overline{X}_{Fj})$ is simply the average of the FM-based ln{emissions):

$$\hat{Y}_{Fj}(\overline{X}_{Fj}) = \overline{Y}_{Fj} = \frac{1}{n_F}\sum_{i=1}^{n_F} y_{ij} \tag{D-2}$$

where n_F is the number of FM-based measurements, y_{ij} = i^{th} observed ln(emission) for vehicle *j*, and the summation is over the FM-based measurements. On the other hand, $\hat{Y}_{Bj}(\overline{X}_{Fj})$ must be estimated based on the assumed baseline relationship between Y and X. If this relationship is assumed to be linear, then a statistical model for simultaneously estimating Δ_j and the parameters of the linear baseline relationship is the following:

$$y_{ij} = \alpha_j + \Delta_j Z_{ij} + \beta_j(x_{ij} - \overline{X}_{Fj}) + \varepsilon_{ij} \tag{D-3}$$

where

y_{ij} = i^{th} observed ln(emission) for vehicle *j*,
x_{ij} = mileage associated with i^{th} observation for vehicle *j*,
Z_{ij} = 1 if i^{th} observation for j^{th} vehicle is for FM-based condition,
= 0, otherwise,
ε_{ij} = random error for i^{th} observation for vehicle *j*, and

α_j, Δ_j, and $+\beta_j(x)$ are parameters to be estimated. With the model parameters defined in this way, the resulting estimates from a least squares regression are as follows:

US EPA ARCHIVE DOCUMENT

$\hat{\alpha}_j = \hat{Y}_{Bj}(\overline{X}_{Fj})$ = estimated baseline (ln-scale) emissions at the mileage where the FM-based tests are conducted,

$\hat{\Delta}_j$, as defined by Equation (D-1), is the estimated effect of the FM, and

$\hat{\beta}_j = \dfrac{\sum_{i=1}^{n_B} x_{ij} y_{ij} - n_B \overline{X}_{Bj} \overline{Y}_{Bj}}{\sum_{i=1}^{n_B} x_{ij}^2 - n_B \overline{X}_{Bj}^2}$ = estimated deterioration rate under baseline conditions,

where n_B is the total number of baseline measurements and $\overline{Y}_{Bj}$ is the mean of the n_B baseline measurements. It should be noted that this slope estimate is identical to the least squares estimate that would be obtained if only baseline data were included in the regression. Standard multiple regression software can therefore be used to produce both an estimate of the desired FM effect and of its standard error. Hence, confidence interval estimates for $\hat{\Delta}_j$ (or hypothesis tests) are straightforward. The variance of the estimated effect can be estimated as

$$Var[\hat{\Delta}_j] = s_j^2 \left[\frac{1}{n_F} + \frac{1}{n_B} + \frac{(\overline{X}_{Fj} - \overline{X}_{Bj})^2}{\sum_{i=1}^{n_B} x_{ij}^2 - n_B \overline{X}_{Bj}^2} \right] \quad \text{(D-4)}$$

where s_j^2 is the residual variance from the multiple regression performed on the vehicle *j* data. (If the model is accurate, then s_j^2 is an estimate of the measurement error variance of the emissions.) The degrees of freedom associated with Equation D-4 is $n_F + n_B - 3$.

The primary single-vehicle hypothesis of interest is the following:

$$H_0: \Delta_j = 0 \text{ vs. } H_A: \Delta_j < 0 \quad \text{(D-5)}$$

This is tested by computing a t statistic on the estimated effect, $\hat{\Delta}_j$,

$$t = \frac{\hat{\Delta}_j}{\sqrt{Var(\hat{\Delta}_j)}} \quad \text{(D-6)}$$

and comparing the result to t_C, the 5th percentage point of a t distribution with $n_F + n_B - 3$ degrees of freedom (e.g., if the total sample size is 24, then $t_C = -1.721$). The null hypothesis, H_0, is rejected if $t < t_C$.

To achieve the desired ETV confidence level (95%) and level of statistical power (90% at the applicant's anticipated effect level) for testing this hypothesis, one must ensure that the variance

US EPA ARCHIVE DOCUMENT

in Equation (D-4) is sufficiently small. Clearly, the magnitude on Equation (D-4) depends not only on the sample sizes and the underlying measurement error variance, but also on the design – namely, the spacing of the mileage points and the amount of replicate testing at each of those points. In general, smaller variance will be achieved by increasing the dispersion of the baseline mileage points used in the regression and/or by decreasing the absolute difference between $\overline{X}_{Fj}$ and $\overline{X}_{Bj}$. Note that all of the quantities appearing inside the brackets of Equation (D-4) depend solely on the particular design used. Hence, for any given design, the power of the test can be determined as follows.

- First determine the degrees of freedom and critical value, t_C, of the test, as defined above (e.g., select the 95th percentage point from a table of percentage points of the t distribution).

- Based on prior data, assume a value for the true underlying measurement error variance; denote this quantity as σ^2.

- Then compute a noncentrality parameter, *D*, as

$$D = \frac{\delta}{\sqrt{\sigma^2 K_j}} \qquad \text{(D-7)}$$

  where δ is the anticipated effect (in ln-scale units, or relative difference) and K_j is the quantity inside the brackets in Equation (C-4). (Given the formulation of the hypothesis test, δ should be negative.)

- The power (the probability of rejecting the null hypothesis when a true effect is equal to δ) is then determined as

$$\Pr[T(D) < t_C] \qquad \text{(D-8)}$$

  where T(D) denotes a random variable following a noncentral t distribution with noncentrality parameter D and $n_F + n_B - 3$ degrees of freedom. (Standard statistical software packages such as S-Plus or SAS have built-in functions for calculating such percentage points from noncentral t distributions.)

- By varying the design and/or the sample sizes, one can determine when Equation (D-8) exceeds 0.90, the desired power.

US EPA ARCHIVE DOCUMENT

US EPA ARCHIVE DOCUMENT

APPENDIX E: SINGLE VEHICLE TESTS FOR LUBRICANTS

Assume that emission measurements are made at each of four mileage points within each of three phases, as indicated in Figure 2 of the generic verification protocol. In particular, assume that phase 2 consists of tests for the candidate FM and that phases 1 and 3 consist of baseline measurements. Note the following characteristics regarding the mileage scale of the design:

- The within-phase designs are the same for each phase. They can be characterized by a variable *U*, which is the mileage since oil change. Let U_{ijk} = the mileage since last oil change for measurement *i* within phase *k* for vehicle *j*, and let $\overline{U_{ik}}$ denote the average of these mileages for phase *k* of vehicle *j*. Let $u_{ijk} = U_{ijk} - \overline{U}_{jk}$ be the deviation of these mileages from their respective phase-specific means. (Nominally, the mileages within a phase are equally spaced, so that the four *U* values are proportional to 0, 1, 2, and 3; hence the deviations are proportional to -3, -1, 1, and 3.)

- In terms of the mileage scale, phase 2 is centered between phases 1 and 3. Hence, a continuous variable representing phase (with values of 1, 2, and 3) is in fact equivalent, apart from a scale factor and location factor, to a mileage variable. (That is, if the average mileages for the phases are denoted as $\overline{X}_{kj}$ and if deviations from the phase 2 mean are computed, then these deviations will be proportional to -1, 0, and 1, respectively, for phases 1, 2, and 3. This is the same variable as can be obtained by subtracting 2 from the phase indicator, *k*.)

An important consequence of the second bullet is that *the effect of the lubricant FM is totally confounded with a long-term quadratic deterioration effect*. To see this, *assume for the moment that phase 2 also involves baseline measurements* and assume that (a) within-phase deterioration effects are linear, and (b) that long-term (i.e., across phases or oil changes) deterioration effects are potentially quadratic. This corresponds to a saw-toothed curve with linear segments within phases that are connected at their midpoints by a second-order curve.

The statistical model for such a situation can be expressed as

$$y_{ijk} = \alpha_{jk} + \beta_{jk} u_{ijk} + \lambda_j L_{ijk} + \Delta_j Q_{ijk} + \epsilon_{ijk} \qquad \text{(E-1)}$$

where

y_{ijk} = i[th] observed ln(emission) for vehicle *j* and phase *k*,
u_{ijk} = within-phase mileage deviation (standardized, if desired [as described above], to take on values of -3, -1, +1, and +3),
L_{ijk} = -1 for phase 1 observations,
= 0 for phase 2 observations,
= +1 for phase 3 observations,
Q_{ijk} = -1/3 for phase 1 observations,
= +2/3 for phase 2 observations,
= -1/3 for phase 3 observations,
ε_{ijk} = random error for i[th] observation for phase *k* and vehicle *j*, and

α_{jk}, β_{jk}, λ_j, and Δ_j are parameters to be estimated.

With the model terms defined in this way, the resulting estimates, indicated by a ^, from a least-squares regression on the vehicle *j* data are as follows:

$$\hat{\alpha}_{jk} = \overline{Y}_{jk} = \text{average ln(emissions) for phase } k \text{ and vehicle } j, \quad \text{(E-2)}$$

$$\hat{\beta}_{jk} = \frac{\sum_{i=1}^{4} u_{ijk} y_{ijk}}{\sum_{i=1}^{4} u_{ijk}^2} = \text{within-phase deterioration factor for vehicle } j, \text{ phase k(expressed in thousand-mile [K] units, where 6K is the number of miles between the first and last tests within a phase),} \quad \text{(E-3)}$$

$$\hat{\lambda}_j = 0.5(\overline{Y}_{j3} - \overline{Y}_{j1}) = \text{linear component of long-term deterioration factor (expressed in phase units), and} \quad \text{(E-4)}$$

$$\hat{\Delta}_j = \overline{Y}_{j2} - \frac{\overline{Y}_{j1} + \overline{Y}_{j3}}{2} = \text{quadratic component of long-term deterioration factor (expressed in phase units).} \quad \text{(E-5)}$$

Now assume that the phase 2 measurements are for the lubricant FM rather than for baseline. Also assume that the long-term deterioration for baseline measurements is linear. This latter assumption is necessary if the effect of the FM for a given vehicle is to be defined as the "average FM emissions for phase 2 minus the baseline emissions that are predicted for phase 2," since we cannot isolate the effect of the FM from the quadratic component of the long-term baseline deterioration factor. For these assumptions, the model of Equation (E-1) still applies, but now Δ_j represents the effect of the FM and its estimate is given by Equation (E-5).

For the given design and the above model, fitting the model of Equation (E-1) to the data for a single vehicle will result in a variance for the estimated FM effect, $\hat{\Delta}_j$, as

$$Var[\hat{\Delta}_j] = 3s_j^2 / 8 \quad \text{(E-6)}$$

where s_j^2 is the residual variance from the multiple regression performed on the vehicle *j* data. (If the model is accurate, then s_j^2 is an estimate of the measurement error variance of the emissions.) The degrees of freedom associated with this variance is 4. The model of Equation (E-1) can also be fit using data from all tested vehicles; in that case, the variance of the estimated FM effect for vehicle *j* is

US EPA ARCHIVE DOCUMENT

$$Var[\hat{\Delta}_j] = 3s_P^2 / 8 \quad \text{(E-7)}$$

where s_P^2 is the (pooled) residual variance from the multiple regression performed on the *m* vehicles in the fleet. The degrees of freedom associated with Equation (E-7) is 4*m*.

Standard multiple regression software can therefore be used to produce both an estimate of the desired FM effect and of its standard error. Hence, confidence interval estimates for Δ_j (or hypothesis tests) are straightforward. The primary single-vehicle hypothesis of interest is the null hypothesis, H_0:$\Delta_j = 0$, versus the alternative hypothesis, H_A:$\Delta_j<0$.

This is tested by computing a t statistic, on the estimated effect, Δ_j,

$$t = \frac{\hat{\Delta}_j}{\sqrt{Var(\hat{\Delta}_j)}} \quad \text{(E-8)}$$

and comparing the result to t_C, the 5th percentage point of a t distribution with 4 or 4*m* degrees of freedom. The null hypothesis, H_0, is rejected if $t < t_C$.

To achieve the desired ETV confidence level (95%) and level of statistical power (90% at the applicant's anticipated effect level) for testing this hypothesis, one must ensure that the variance in Equations (E-6) or (E-7) is sufficiently small. The power of the test can be determined as follows:

- First determine the degrees of freedom and critical value, t_C, of the test, as defined above (e.g., select the 95th percentage point from a table of percentage points of the t distribution).
- Based on prior data, assume a value for the true underlying measurement error variance; denote this quantity as σ^2.
- Then compute a noncentrality parameter as

$$D = \frac{\delta}{\sqrt{\sigma^2 (3/8)}} \quad \text{(E-9)}$$

where δ is the anticipated effect (in ln-scale units, or relative difference). (Given the formulation of the hypothesis test, δ should be negative.)

US EPA ARCHIVE DOCUMENT

- The power, the probability of rejecting the null hypothesis when a true effect is equal to δ, is then determined as

$$\Pr[T(D) < t_C] \qquad \text{(E-10)}$$

where T(D) denotes a random variable following a noncentral t distribution with noncentrality parameter D and 4 or 4*m* degrees of freedom. (Standard statistical software packages such as S-Plus or SAS have built-in functions for calculating such percentage points from noncentral t distributions.)

US EPA ARCHIVE DOCUMENT

APPENDIX F: SENSITIVITY OF NUMBER OF TESTS CALCULATION TO MEASUREMENT VARIABILITY

Table F-1 presents the results of a sensitivity analysis of the calculation of the required number of tests in the particular cases of high (85%) and low (10% and 5%) reductions in emissions. The number of tests reported in the final column is the number required to have a 90% probability of detecting the emissions reduction with 95% confidence. Equation B-3 in Appendix B was used to compute the required number of tests. As in these sections, all calculations utilize the normal distribution under the assumption that the test measurement error is known and constant.

Within Table F-1, the variability of the baseline engine measurement ranges from 2 to 30%, and the controlled engine measurement variability from 10 to 30%. All of the percentage numbers in the table are referenced to a baseline engine emission. To convert the percentages to absolute emission rates, they must be multiplied by a baseline engine emission rate, and at 30% variability the standard deviations are twice the emission rates in g/bhp-hr. The emissions and standard deviations in Table F-1 have all been calculated for a baseline engine emitting PM at the 1990 certification level of 0.6 g/bhp-hr. For example, from the first row, an 85% reduction means an absolute PM emission of 0.09 g/bhp-hr. A 10% controlled engine measurement variability means the standard deviation for that measurement is 0.06 bhp-hr. For the baseline engine, the variability is 2%, so the baseline engine standard deviation is 0.012 bhp-hr. The same approach can be used to make a similar table for any other emission rate by multiplying the percentages by the desired baseline emission rate.

While the number of required tests increases as the test variability increases, Table F-1 shows that the increase is modest at high emissions reduction levels. While higher variability is expected at higher levels of control because the absolute emissions concentrations are low, the large reduction in emissions is easily detected.

On the other hand, lower variability is expected for low emissions reductions, but the smaller changes are harder to detect and more tests are required. Therefore even modest variability levels (relative to those in the top block of Table F-1) lead to very large numbers of tests.

As was discussed in Section 5.1.2, calculation of the confidence intervals on the mean emissions reduction will be based on population statistics and will utilize the t-distribution. Thus, the number of tests calculated using Equation B-3 (population statistics) may be fewer than will be required by the data itself based on sample statistics. As mentioned in Appendix B, an approximate calculation can be made for sample variability utilizing the Student's t-distribution rather than the normal (z-distribution) in Equation B-3. This use of Equation B-3 is not strictly valid, but may be useful for low emission reduction and/or high variability test designs to make a better estimate of the number of tests required.

US EPA ARCHIVE DOCUMENT

Table F-1. Sensitivity of Number of Tests to Measurement Variability

Expected emissions reduction, %	Controlled engine emissions, g/bhp-hr, relative to a baseline engine at the 1990 PM certification emission limit	Controlled engine variability, % of baseline engine	Controlled engine standard deviation, g/bhp-hr for baseline emission of 0.6 g/bhp-hr	Baseline engine variability, %, with the 1990 certification limit as baseline	Baseline engine standard deviation, g/bhp-hr, for1990 emission limit baseline emission of 0.6 g/bhp-hr	Number[a] of tests to achieve 90% probability of detecting reduction with 95% confidence

Final Regulation Order

California Code of Regulations, Title 13, Division 3

Chapter 14. Verification Procedure, Warranty and In-Use Compliance Requirements for In-Use Strategies to Control Emissions from Diesel Engines

§ 2700. Applicability.

These procedures apply to in-use strategies which, through the use of sound principles of science and engineering, control emissions of particulate matter (PM) and oxides of nitrogen (NOx) from diesel-fueled diesel engines. These strategies may include but are not limited to, diesel particulate filters, diesel oxidation catalysts, fuel additives, selective catalytic reduction systems, exhaust gas recirculation systems, and alternative diesel fuels. To be verified under these procedures, a strategy must either reduce emissions of PM or both PM and NOx. A strategy that reduces emissions of NOx alone may be verified only for use with on-road diesel engines certified to a PM emissions standard of 0.01 grams per brake-horsepower hour (g/bhp-hr) or less, or off-road diesel engines certified to a PM emissions standard of 0.03 g/bhp-hr or less. A strategy that reduces emissions of NOx alone may be verified for use with other diesel engines provided that they are not regulated by ARB in-use fleet regulations or Airborne Toxic Control Measures that require PM emissions control, or provided that they would otherwise potentially not be retrofit with PM emission control strategies.

NOTE: Authority cited: Sections 39002, 39003, 39500, 39600, 39601, 39650-39675, 40000, 43000, 43000.5, 43011, 43013, 43018, 43105, 43600 and 43700, Health and Safety Code. Reference: Sections 39650-39675, 43000, 43009.5, 43013, 43018, 43101, 43104, 43105, 43106, 43107 and 43204-43205.5 Health and Safety Code; and Title 17 California Code of Regulations Section 93000.

§ 2701. Definitions.

(a) The definitions in Section 1900(b), Chapter 1, Title 13 of the California Code of Regulations are incorporated by reference herein. The following definitions shall govern the provisions of this chapter:
  (1) “15 ppmw or less sulfur fuel” means diesel fuel with a sulfur content equal to or less than 15 parts per million by weight (ppmw).
  (2) “Advertise” means to provide any notice, announcement, information, publication, catalog, listing for sale or lease, or other statement concerning a product or service to the public for the purpose of furthering the sale or lease of the product or service.
  (3) “Alternative Diesel Fuel” means any fuel used in diesel engines that is not commonly or commercially known, sold or represented as diesel fuel No. 1-D or No. 2-D, pursuant to the specifications in ASTM Standard Specification for Diesel Fuel Oils D975-81 and does not require engine or

fuel system modifications for the engine to operate, although minor modifications (e.g. recalibration of the engine fuel control) may enhance performance. Examples of alternative diesel fuels include, but are not limited to, biodiesel, Fischer Tropsch fuels, and emulsions of water in diesel fuel. Natural gas is not an alternative diesel fuel. An emission control strategy using a fuel additive will be treated as an alternative diesel fuel based strategy unless:

(A) The additive is supplied to the vehicle or engine fuel by an on-board dosing mechanism, or

(B) The additive is directly mixed into the base fuel inside the fuel tank of the vehicle or engine, or

(C) The additive and base fuel are not mixed until vehicle or engine fueling commences, and no more additive plus base fuel combination is mixed than required for a single fueling of a single engine or vehicle.

(4) "Approach Light System with Sequenced Flasher Lights in Category 1 and Category 2 Configurations" (ALSF-1 and ALSF-2) mean high intensity approach lighting systems with sequenced flashers used at airports to illuminate specified runways during category II or III weather conditions, where category II means a decision height of 100 feet and runway visual range of 1,200 feet, and category III means no decision height or decision height below 100 feet and runway visual range of 700 feet.

(5) "Applicant" means the entity that has applied for or has been granted verification under this Procedure.

(6) "Auxiliary Emission Control Device" (AECD) means any device or element of design that senses temperature, vehicle speed, engine revolutions per minute (RPM), transmission gear, manifold vacuum, or any other parameter for the purpose of activating, modulating, delaying, or deactivating the operation of the emission control system.

(7) "Average" means the arithmetic mean.

(8) "Backpressure Monitor" means a device that includes a sensor for measuring the engine backpressure upstream of a hardware-based diesel emission control system or component thereof installed in the exhaust system and an indicator to notify the operator when the backpressure exceeds specified high and in some cases low backpressure limits, as defined by the engine manufacturer or the applicant for verification of a diesel emission control strategy.

(9) "Baseline" means the test of a vehicle or engine without the diesel emission control strategy implemented.

(10) "Cold Start" means the start of an engine only after the engine oil and water temperatures are stabilized between 68 and 86 degrees Fahrenheit for a minimum of 15 minutes.

(11) "Common ownership fleet" means all off-road and on-road vehicles and stationary engines being owned or managed day to day by the same person, corporation, partnership, or association. Vehicles managed by the same directors, officers, or managers, or by corporations controlled

by the same majority stockholders are considered to be under common ownership or control even if their title is held by different business entities. For purposes of this regulation, on-road, off-road vehicles and stationary engines are to be considered separate fleets.

(12) "Component Swapping" means the movement of designated parts between different vehicles/applications utilizing the same DECS.

(13) "Diesel emission control strategy" or "Diesel emission control system" means any device, system, or strategy employed with an in-use diesel vehicle or piece of equipment that is intended to reduce emissions. Examples of diesel emission control strategies include, but are not limited to, particulate filters, diesel oxidation catalysts, selective catalytic reduction systems, fuel additives used in combination with particulate filters, alternative diesel fuels, and combinations of the above.

(14) "Diesel Emission Control Strategy Family Name." See Section 2706(j)(2).

(15) "Diesel Engine" means an internal combustion engine with operating characteristics significantly similar to the theoretical diesel combustion cycle. The primary means of controlling power output in a diesel cycle engine is by limiting the amount of fuel that is injected into the combustion chambers of the engine. A diesel cycle engine may be petroleum-fueled (i.e., diesel-fueled) or alternate-fueled.

(16) "Distributor" means any person or entity to whom a diesel emission control strategy is sold, leased or supplied for the purposes of resale or distribution in commerce.

(17) "Donor Vehicle/engine" means any vehicle/engine whose installed DECS device has been removed for the purpose of re-designation or component swapping.

(18) "Durability" means the ability of the applicant's diesel emission control strategy to maintain a level of emissions below the baseline and maintain its physical integrity over some period of time or distance determined by the Executive Officer pursuant to these regulations. The minimum durability testing periods contained herein are not necessarily meant to represent the entire useful life of the diesel emission control strategy in actual service.

(19) "Emergency Standby Engine" means a diesel engine operated solely for emergency use, except as otherwise provided in airborne toxic control measures adopted by the ARB.

(20) "Emergency Use" means using a diesel engine to provide electrical power or mechanical work during any of the following events and subject to the following conditions:

(A) The failure or loss of all or part of normal electrical power service or normal natural gas supply to the facility,

(B) The failure of a facility's internal power distribution system,

(C) The pumping of flood water or sewage to prevent or mitigate a flood or sewage overflow,

(D) The pumping of water for fire suppression or protection,

(E) The powering of ALSF-1 and ALSF-2 airport runway lights under category II or III weather conditions,
(F) Other conditions as specified in airborne toxic control measures adopted by the ARB.

(21) “Emission control group” means a set of diesel engines and applications determined by parameters that affect the performance of a particular diesel emission control strategy. The exact parameters depend on the nature of the diesel emission control strategy and may include, but are not limited to, certification levels of engine emissions, combustion cycle, displacement, aspiration, horsepower rating, duty cycle, exhaust temperature profile, and fuel composition. Verification of a diesel emission control strategy and the extension of existing verifications are done on the basis of emission control groups.

(22) “End user” means any individual or entity that owns or operates a vehicle or piece of equipment that has a verified diesel emission control system installed.

(23) “Executive Officer” means the Executive Officer of the Air Resources Board or the Executive Officer’s designee.

(24) “Executive Order” means the document signed by the Executive Officer that specifies the verification level of a diesel emission control strategy for an emission control group and includes any enforceable conditions and requirements necessary to support the designated verification.

(25) “Fuel Additive” means any substance designed to be added to fuel or fuel systems or other engine-related systems such that it is present in-cylinder during combustion and has any of the following effects: decreased emissions, improved fuel economy, increased performance of the entire vehicle or one of its component parts, or any combination thereof; or assists diesel emission control strategies in decreasing emissions, or improving fuel economy or increasing performance of a vehicle or component part, or any combination thereof. Fuel additives used in conjunction with diesel fuel may be treated as an alternative diesel fuel. See Section 2701 (a)(3) .

(26) “Hot Start” means the start of an engine within four hours after the engine is last turned off. The first hot start test run should be initiated 20 minutes after the cold start for Federal Test Procedure testing following Section 86.1327-90 of the Code of Federal Regulations, Title 40, Part 86.

(27) “Installer” means any individual or entity that equips any vehicle, engine or equipment with a diesel emission control strategy.

(28) “Portable Engine” means an engine designed and capable of being carried or moved from one location to another, except as defined in section 2701(a)(33). Engines used to propel mobile equipment or a motor vehicle of any kind are not portable. Indicators of portability include, but are not limited to, wheels, skids, carrying handles, dolly, trailer, or platform. A portable engine cannot remain at the same facility location for more than 12 consecutive rolling months or 365 rolling days, whichever occurs first, not including time spent in a storage facility. If it

does remain at the facility for more than 12 months, it is considered to be a stationary engine. The definitions in Title 13 California Code of Regulations section 2452(g) and section 2452(x) are incorporated by reference herein.

(29) "Re-designation" means the movement of a used verified DECS from an appropriate engine/application and installation to another engine/application meeting the terms and conditions of the DECS Executive Order within the same common ownership fleet.

(30) "Regeneration" in the context of diesel particulate filters, means the periodic or continuous combustion of collected particulate matter that is trapped in a particulate filter through an active or passive mechanism. Active regeneration requires a source of heat other than the exhaust itself to regenerate the particulate filter. Examples of active regeneration strategies include, but are not limited to, the use of fuel burners and electrical heaters. Passive regeneration does not require a source of heat for regeneration other than the exhaust stream itself. Examples of passive regeneration strategies include, but are not limited to, the use of fuel additives and the catalyst-coated particulate filter. In the context of NOx reduction strategies, "regeneration" means the desorption and reduction of NOx from NOx adsorbers (or NOx traps) during rich operation conditions.

(31) "Revoke" means to cancel the verification status of a diesel emission control strategy. If a diesel emission control strategy's verification status is revoked by the Executive Officer, the applicant must immediately cease and desist selling the diesel emission control strategy to end-users.

(32) "Seller" means any person or entity that sells, leases or supplies a diesel emission control strategy.

(33) "Stationary Engine" means an engine that is designed to stay in one location, or remains in one location. An engine is stationary if any of the following are true:

(A) The engine or its replacement is attached to a foundation, or if not so attached, will reside at the same location for more than 12 consecutive months. Any engine that replaces engine(s) at a location, and is intended to perform the same or similar function as the engine(s) being replaced, will be included in calculating the consecutive time period. In that case, the cumulative time of all engine(s), including the time between the removal of the original engine(s) and installation of the replacement engine(s), will be counted toward the consecutive time period; or

(B) The engine remains or will reside at a location for less than 12 consecutive months if the engine is located at a seasonal source and operates during the full annual operating period of the seasonal source, where a seasonal source is a stationary source that remains in a single location on a permanent basis (at least two years) and that operates at that single location at least three months each year; or

(C) The engine is moved from one location to another in an attempt to circumvent the residence time requirements [Note: The period during which the engine is maintained at a storage facility shall be excluded from the residency time determination.] The definitions in Title 13 California Code of Regulations Section 2452(g) and Section 2452(x) are incorporated by reference herein.

(34) "Unidirectional Device Design and Installation" means that an emission control device must be appropriately designed, manufactured and labeled to prevent reverse flow installation.

(35) "Used Verified Device" means any verified DECS which has been sold or leased to an end user and installed on an engine/application.

(36) "Verification" means a determination by the Executive Officer that a diesel emission control strategy meets the requirements of this Procedure. This determination is based on both data submitted or otherwise known to the Executive Officer and engineering judgment.

(37) "Warrantable Condition" means any condition of the diesel emission control strategy, vehicle, or engine which triggers the responsibility of the applicant to take corrective action pursuant to Section 2707.

NOTE: Authority cited: Sections 39002, 39003, 39500, 39600, 39601, 39650-39675, 40000, 43000, 43000.5, 43011, 43013, 43018, 43105, 43600 and 43700, Health and Safety Code. Reference: Sections 39650-39675, 43000, 43009.5, 43013, 43018, 43101, 43104, 43105, 43106, 43107 and 43204-43205.5, Health and Safety Code; and Title 17 California Code of Regulations Section 93000.

§ 2702. Application Process.

(a) Overview. Before submitting a final application for the verification of a diesel emission control strategy for use with an emission control group, the applicant must submit a preliminary verification application (pursuant to Section 2702(b)) at the Executive Officer's discretion in the format shown in 2702(d). To obtain verification, the applicant must conduct emission reduction testing (pursuant to Section 2703), durability testing (pursuant to Section 2704), a field demonstration (pursuant to Section 2705), and submit the results along with comments and other information (pursuant to Sections 2706 and 2707) in a final verification application to the Executive Officer, in the format shown in Section 2702(d). If the Executive Officer grants verification of a diesel emission control strategy, it will issue an Executive Order to the applicant identifying the verified emission reduction and any conditions that must be met for the diesel emission control strategy to function properly. After the Executive Officer grants verification of a diesel emission control strategy, the applicant must provide a warranty, conduct in-use compliance testing of the strategy after having sold or leased a specified number of units, and report the results to the Executive Officer (pursuant to Section 2709). A diesel emission control strategy that employs two or more individual systems or

components must be tested and submitted for evaluation as one system. A verified diesel emission control strategy may not be installed on an engine with another diesel emission control strategy that is not included in the Executive Order. Applicants seeking verification of an alternative diesel fuel must follow the procedure described in Section 2710.

(b) Preliminary Verification Application. Before formally submitting a final application for the verification of a diesel emission control strategy, the applicant must submit a preliminary verification application at the Executive Officer's discretion. The Executive Officer shall use the information in the preliminary verification application to help determine whether the strategy relies on sound principles of science and engineering to control emissions, the need for additional analyses, and the appropriateness of allowing alternatives to the prescribed requirements. The preliminary verification application must follow the format shown in Section 2702(d) and at a minimum provide the information required in sections 1. through 5., and section 8.A.5, where applicable. In addition, the preliminary verification application must include the following information:

(1) Identification of the contact persons, phone numbers, names and addresses of the responsible party submitting the preliminary verification application.

(2) Description of the diesel emission control strategy's principles of operation. A schematic depicting operation must be included. It is the responsibility of the applicant to demonstrate that its product relies on sound principles of science and engineering to achieve emission reductions.

(A) If, after reviewing the preliminary verification application, the Executive Officer determines that the applicant has not made a satisfactory demonstration that its product (diesel emission control strategy) relies on sound principles of science and engineering to achieve emission reductions, the Executive Officer shall notify the applicant of the determination in writing within 30 days of receiving the preliminary verification application. The applicant may choose to withdraw from the verification process or submit additional materials and clarifications. The additional submittal must be received by the Executive Officer no later than 60 days from the date of the notification letter or the application may be suspended.

(B) If, after reviewing the additional submittal, the Executive Officer determines that the applicant has not yet made a satisfactory demonstration that its product relies on sound principals of science and engineering to achieve emission reductions, the preliminary verification application shall be suspended. If a preliminary verification application has been suspended, it may only be reactivated at the discretion of the Executive Officer.

(C) If at any time, the Executive Officer has reason to doubt the scientific or engineering soundness of a product, the Executive Officer shall notify the applicant in writing and may require the applicant to submit

additional supporting materials and clarifications no later than 60 days from the date of the notification letter. If the additional submittal is not received by the Executive Officer by the deadline established in the notification letter, the preliminary or final application may be suspended or the existing verification may be revoked. In deciding whether to suspend a preliminary or final application or revoke an existing verification the Executive Officer will review submittals as provided in subsection (B) above.

(3) Preliminary parameters for defining emission control groups that are appropriate for the diesel emission control strategy. The Executive Officer will work with the applicant to determine appropriate emission control group parameters.

(4) The applicant's proposed test plan for meeting the requirements of Sections 2702-2706. Existing test data may be submitted for the Executive Officer's consideration. The preliminary verification application must focus on verification of the diesel emission control strategy for use with a single emission control group.

(5) A brief statement that the applicant acknowledges and agrees to do the following:

(A) Provide a warranty pursuant to the requirements of Section 2707.

(B) Submit in-use compliance information pursuant to the requirements of Section 2709.

(C) Keep records until the in-use compliance requirements are completed that contain information per Section 2702 (m) including:

1. Updated end user contact information.
2. A description of the vehicles or equipment on which the applicant's products are installed.
3. A description of the engines on which the applicant's products are installed.

(c) When an applicant submits a preliminary verification application, the Executive Officer shall, within 30 days of its receipt, determine whether the applicant has identified the information necessary to support an application for verification and notify the applicant in writing that it may submit an application for verification. The Executive Officer may suggest modifications to the proposed preliminary verification application to facilitate verification of the diesel emission control strategy. All applications, correspondence, and reports must be submitted in writing to:

Chief, Heavy-Duty Diesel In-Use Strategies Branch
Air Resources Board
1001 I Street
Sacramento, CA 95814

(d) Application Format. The preliminary and final verification applications must be submitted in writing to the address shown in subsection (c) above. Electronic mail and verbal submissions do not constitute acceptable application formats. Supporting data in electronic format may be accepted as part of the application at the discretion of the Executive Officer. The preliminary and final verification applications for a diesel emission control strategy must follow the format shown below. If a section asks for information that is not applicable to the diesel emission control strategy, the applicant must indicate "not applicable." If the Executive Officer concurs with the applicant's judgment that a section is not applicable, the Executive Officer may waive the requirement to provide the information requested in that section. Final verification applications must include all of the information provided in the preliminary verification application as described in Section 2702(b), including any additional information, updates, or changes, and all additional information shown below.

1. Introduction

1.1 Identification of applicant, manufacturer, and product
1.2 Identification of type of verification being sought
- 1.2.1 Description of emission control group selected
- 1.2.2 Emission reduction claim
- 1.2.3 Description of intended applications (examples of in-use vehicles or equipment, typical duty cycles, fuel requirements, etc.)

2. Diesel Emission Control Strategy Information

2.1 General description of the diesel emission control strategy
- 2.1.1 Detailed discussion of principles of operation and system design
- 2.1.2 Description of inducement method if applicable
- 2.1.3 Schematics depicting operation (as appropriate)
- 2.1.4 A list identifying all the parts of the diesel emission control strategy as described in Section 2706(o)
- 2.1.5 Detailed description of measures taken to prevent reverse flow installation

2.2 Description of regeneration method
- 2.2.1 Operating condition requirements for regeneration
- 2.2.2 Thresholds and control logic to activate regeneration
- 2.2.3 Description of backpressure monitor including thresholds and control logic

2.3 Favorable operating conditions
2.4 Unfavorable operating conditions and associated reductions in performance
2.5 Fuel and lubricating oil requirements and misfueling considerations
2.6 Identification of failure modes and associated consequences

2.7 Complete discussion of potential safety issues *(e.g., uncontrolled regeneration, lack of proper maintenance, unfavorable operating conditions, etc.)*
2.8 Installation requirements
2.9 Maintenance requirements
2.9.1 Detailed description of all normal maintenance requirements for the diesel emission control system
2.9.2 A copy of the language that will instruct the end user of proper handling of spent components and/or materials cleaned from the diesel emission control system, identify any hazardous materials, and provide procedures for resetting any backpressure monitors after maintenance procedures are completed.
2.10 Description of noise level control compliance

3. Alternative Diesel Fuel and Fuel Additive Information.
(Use of an alternative diesel fuel/fuel additive requires a multimedia evaluation as required by Section 43830.8 California Health and Safety Code)
3.1 Additional information from Section 2710(b), 2710(c), 2710(f), and 2710(g)
3.2 Emission control group compatibility considerations
3.3 Misfueling prevention strategies
3.4 Multimedia evaluation
3.4.1 Additional test data and information required for multimedia evaluation

4. Diesel Emission Control Strategy and Emission Control Group Compatibility
4.1 Compatibility with the engine
4.1.1 Discussion on calibrations and design features that may vary from engine to engine
4.1.2 Effect on overall engine performance
4.1.3 Effect on engine backpressure
4.1.4 Additional load on the engine
4.1.5 Effect on fuel consumption
4.1.6 Engine oil consumption considerations
4.2 Compatibility with the application
4.2.1 Dependence of calibration and other design features on application characteristics
4.2.2 Presentation of typical exhaust temperature profiles and other relevant field-collected data from representative applications within the emission control group
4.2.3 Comparison of field-collected application data with operating conditions suitable for the diesel emission control strategy

5. Testing Information
5.1 Emission reduction testing
5.1.1 Test facility identification including capabilities and identification of all analytical instruments

5.1.2 Description of test vehicle and engine *(make, model year, engine family name, PM and NOx certification levels if applicable, etc.)*
5.1.3 Statement indicating whether the test engine is in a proper state of maintenance, and/or has been rebuilt or modified from the original engine manufacturer configuration
5.1.4 Description of test fuel
5.1.5 Discussion of effects of elevated NOx emissions on diesel emission control strategy (effects on emission reduction performance, durability, safety, and control strategy response)
5.1.6 Test procedure description *(-pre-conditioning period, test cycle, etc.)*
5.1.7 Test results and comments
5.1.8 Incomplete and aborted test data and explanations

5.2 Durability testing
5.2.1 Test facility identification including capabilities and identification of all analytical instruments
5.2.2 Description of field application (where applicable)
5.2.3 Description of test vehicle and engine *(make, model year, engine family name, PM and NOx certification levels if applicable, etc.)*
5.2.4 Analysis of emissions test fuel
5.2.5 Analysis of durability test fuel
5.2.6 Test procedure description *(field or bench, test cycle, etc.)*
5.2.7 Test Procedure demonstrating durability of monitoring and notification system
5.2.8 Description of maintenance during durability testing
5.2.9 Test results and comments
5.2.10 Summary of evaluative comments from third-party for in-field durability demonstration *(e.g., driver or fleet operator)*

5.3 Field demonstration (where applicable)
5.3.1 Field application identification
5.3.2 Description of test vehicle and engine *(make, model year, engine family name, PM and NOx certification levels if applicable, etc.)*
5.3.3 Engine backpressure and exhaust temperature graphs with comments
5.3.4 Summary of evaluative comments from third-party *(e.g., driver or fleet operator)*
5.3.5 Description of test failures

*6***.** *Warranty and In-Use Compliance Requirements*

6.1 Statement that the applicant agrees to provide annual warranty reports and to follow the warranty requirements per Section 2707
6.2 Statement that the applicant agrees to follow the in-use compliance requirements per Section 2709
6.3 Statement that the applicant agrees to keep the required end user information per Section 2702(m)

7. *References*

8. *Appendices*

A. Laboratory test report information *(for all tests, including incomplete, aborted and failed tests)*
   - A.1 Actual laboratory test data
   - A.2 Plots of engine backpressure and exhaust temperature
   - A.3 Driving traces for chassis dynamometer tests
   - A.4 Quality assurance and quality control information
   - A.5 Testing equipment information and indication that testing equipment meets specifications and calibrations given in the Code of Federal Regulations, Title 40, Part 86 (See Sections 2703(m), 2706(a)(2))

B. Third-party letters or questionnaires describing in-field performance
C. Diesel emission control system label
D. Copy of the Owner's manual (as described in Section 2706 (l))
E. Copy of the Installation Manual
F. Sample diesel emission control system label (See Section 2706(j))
G. Other supporting documentation

(e) Within 30 days of receipt of the preliminary application, the Executive Officer shall notify the applicant whether the application is complete.

(f) Within 60 days after a final application has been deemed complete, the Executive Officer shall determine whether the diesel emission control strategy merits verification and shall classify it as shown in Table 1:

Table 1. Verification Classifications for Diesel Emission Control Strategies

Pollutant	Reduction	Classification
PM	< 25%	Not verified
		Level 0* (see note below)
	≥ 25%	Level 1
		Level 1 Plus**
	≥ 50%	Level 2
		Level 2 Plus**
	≥ 85%, or ≤ 0.01 g/bhp-hr	Level 3
		Level 3 Plus**
NOx	< 25%	Not verified
	≥ 25%	Mark 1
	≥ 40%	Mark 2
	≥ 55%	Mark 3
	≥ 70%	Mark 4
	≥ 85%	Mark 5

*A diesel emission control strategy that reduces emissions of PM by less than 25 percent may be verified as a Level 0 strategy if it reduces emissions of NOx by at least 25 percent and meets the other criteria in section 2700.
**The diesel emission control strategy complies with the 20 percent NO_2 limit before January 1, 2009 (and after January 1, 2007).

The applicant and the Executive Officer may mutually agree to a longer time period for reaching a decision, and additional supporting documentation may be submitted by the applicant before a decision has been reached. The Executive Officer shall notify the applicant of the decision in writing and specify the verification level for the diesel emission control strategy and identify any terms and conditions that are necessary to support the verification.

(g) Extensions of an Existing Verification. If the applicant has verified a diesel emission control strategy with one emission control group and wishes to extend the verification to include additional emission control groups, it may apply to do so using the original test data, additional test data, engineering justification and analysis, or any other information deemed necessary by the Executive Officer to address the differences between the emission control

group already verified and the additional emission control group(s). Processing time periods follow sections (e) and (f) above.

(h) Conditional Extensions of an Existing Verification for On-road Applications. If an applicant has an ARB verified diesel emission control strategy and wishes to extend the verification to include new on-road emission control groups, the applicant may apply to receive a conditional extension. If the Executive Officer determines that the diesel emission control strategy is technologically sound and appropriate for the intended application, the applicant may be granted a conditional extension for up to one year. Upon receiving a conditional extension, the applicant may sell the diesel emission control strategy as a verified product for the duration of the conditional extension period. To obtain full verification, the applicant must complete the requirements set forth by the Executive Officer according to the requirements of the regulation. In granting a conditional extension, the Executive Officer may consider all relevant information including, but not limited to, the following: the design of the diesel emission control strategy, original test data, other relevant test data, the duty cycle of the prospective emission control group, and field experience. For the time period it is effective, a conditional extension is equivalent to a verification for the purposes of satisfying the in-use compliance requirements. Emission control strategies that are conditionally verified for off-road and stationary applications are not eligible for conditional extensions (See Section 2704(k)).

(i) Design Modifications. If an applicant modifies the design of a diesel emission control strategy that has already been verified or is under consideration for verification by the Executive Officer, the modified version must be evaluated under this Procedure. The applicant must provide a detailed description of the design modification along with an explanation of how the modification will change the operation and performance of the diesel emission control strategy. To support its claims, the applicant must submit additional test data, engineering justification and analysis, or any other information deemed necessary by the Executive Officer to address the differences between the modified and original designs. Processing time periods follow sections (e) and (f) above.

(j) Verification Transfers. If an applicant wishes to sell, lease, or supply another manufacturer's previously verified diesel emission control system, the applicant must do the following:
   (1) Submit a letter of consent from the manufacturer that legally holds the original verification. The letter must give the applicant the right to hold a verification for the diesel emission control system and, if applicable, to use information that was previously submitted as support in the application for the original verification.
   (2) Submit an application(s) per Section 2702 of this Procedure. If previously submitted information is included, necessary additional information must

be submitted that satisfies all applicable requirements of this Procedure (e.g. testing data, warranty statement, label, owner's manual, etc.).

(3) Submit a description of the diesel emission control strategy's principles of operation. The applicant must demonstrate understanding of how the product relies on sound principles of science and engineering to achieve emissions reductions.

(k) Emission Control Systems Approved under Other Verification Programs. Any applicant with a diesel emission control system that is verified under another diesel emission control verification program that wishes to receive ARB verification must submit an application that contains the information requested in part (d) above. Pre-existing data and information submitted in support of verification approval from other programs may be submitted, but the applicant must meet requirements that are unique to this Procedure including, but not limited to, a system label compliant with Section 2706(j), a California owner's manual compliant with Section 2706(l), a warranty compliant with Section 2707, in-use compliance requirements per Section 2709, and multimedia evaluation if applicable. The Executive Officer may evaluate all information submitted including additional information required by this Procedure to determine if a diesel emission control strategy merits ARB verification.

(l) Treatment of Confidential Information. Information submitted to the Executive Officer by an applicant may be claimed as confidential, and such information shall be handled in accordance with the procedures specified in Title 17, California Code of Regulations, Sections 91000-91022. The Executive Officer may consider such confidential information in reaching a decision on a verification application.

(m) Applicants that receive verifications, conditional verifications (See Section 2704(k), or conditional extensions must keep records that have valid end user contact information (name, address, phone number), a description of the vehicles or equipment the units are applied to (type of vehicle/equipment, make, model year, vehicle identification number), and a description of the engines the units are applied to (make, model, model year, engine serial number, engine family name). The applicant must keep these records for each diesel emission control strategy family until the in-use compliance requirements of the diesel emission control strategy family are completed. Applicants that receive conditional extensions or conditional verifications must submit these records to the Executive Officer one year after receiving the conditional extension or conditional verification. Applicants that receive verifications must submit these records upon request by the Executive Officer to an agent or employee of ARB. The Executive Officer may request that such records be made available at any time. The applicant must provide these records within 30 days of the request by the ARB. Failure to submit these records may result in revocation or suspension of the verification

and/or any other remedy available under Part 5, Division 26 of the Health and Safety Code.

(n) The Executive Officer may at any time with respect to any diesel emission control strategy sold, leased, offered for sale, intended for sale, or manufactured for sale in California, order the applicant or manufacturer to submit records pertaining to the diesel emission control strategy, at the applicant's expense, to a location specified by the Executive Officer.

(o) Applicants that receive verifications, conditional verifications, or conditional extensions must demonstrate sales or the active pursuit of sales of their diesel emission control systems in California upon request of the Executive Officer. If an applicant fails to provide such proof, the Executive Officer will evaluate whether the verification should be revoked.

(p) The Executive Officer may, with respect to any diesel emission control strategy sold, leased, offered for sale, intended for sale, or manufactured for sale in California, order the applicant or strategy manufacturer to make available for testing and/or inspection a reasonable number of diesel emission control systems, and may direct that they be delivered at the applicant's expense to the state board at the Haagen-Smit Laboratory, 9528 Telstar Avenue, El Monte, California or where specified by the Executive Officer. The Executive Officer may also, with respect to any diesel emission control strategy being sold, leased, offered for sale, intended for sale, or manufactured for sale in California, have an applicant test and/or inspect under the supervision of the Executive Officer a reasonable number of units at the applicant's or manufacturer's facility or at any test laboratory accepted by the Executive Officer. All such testing and inspection is confirmatory in nature. If the Executive Officer finds performance that is not consistent with either an existing or requested verification, the applicant must address and resolve the inconsistency to the satisfaction of the Executive Officer in order to maintain or receive verification. Any testing and inspection done by ARB cannot be used as a substitute for emissions test data or other support required in an application for verification.

(q) The Executive Officer may lower the verification level or revoke the verification status of a verified diesel emission control strategy family, a conditionally verified system, or a system with a conditional extension or suspend all review of pending verification applications if the Executive Officer determines that there are errors, omissions, inaccurate information, fraudulent submittals, or a deficiency of required submittals in the application for verification, supporting information, warranty report, or in-use compliance testing. Additionally, penalties may be assessed under Part 5, Division 26 of the Health and Safety Code. The Executive Officer may suspend the review of all other applications sent by an applicant if that applicant fails to submit warranty reports or other requested information. The Executive Officer may

also seek remedial action against the applicant if it is determined that the verified diesel emission control strategy does not comply with the requirements or provisions of the Executive Order.

NOTE: Authority cited: Sections 39002, 39003, 39500, 39600, 39601, 39650-39675, 40000, 43000, 43000.5, 43011, 43013, 43018, 43105, 43600 and 43700, Health and Safety Code. Reference: Sections 39650-39675, 43000, 43009.5, 43013, 43018, 43101, 43104, 43105, 43106, 43107 and 43204-43205.5, Health and Safety Code; and Title 17 California Code of Regulations Section 93000.

§ 2703. Emission Testing Requirements.

(a) The applicant must test the diesel emission control strategy on an emission control group basis and identify the emission control group. The applicant must identify the test engines and vehicles, if applicable, by providing the engine family name, make, model, model year, and PM and NOx certification levels if applicable. The applicant must also describe the applications for which the diesel emission control strategy is intended to be used by giving examples of in-use vehicles or equipment, characterizing typical duty cycles, indicating any fuel requirements, and/or providing other application-related information.

(b) Test Engine Requirements and Pre-conditioning. The applicant may tune-up or rebuild test engines prior to, but not after, baseline testing unless rebuilding the engine is an integral part of the diesel emission control strategy. All testing should be performed with the test engine in a proper state of maintenance. Emissions of NO_2 from the test engine must not exceed 15 percent of the total baseline NOx emissions by mass. If there is a special category of engines with NO_2 emission levels that normally exceed 15 percent, this requirement may be adjusted for those engines at the discretion of the Executive Officer.

(c) Diesel Emission Control System Pre-conditioning. The engine or vehicle installed with a diesel emission control system must be operated for a break-in period of between 25 and 125 hours before emission testing. Note that special pre-conditioning requirements may apply. See section 2706(a)(4) for details.

(d) Test Fuel.
(1) The test fuel must meet the specifications in the California Code of Regulations (Sections 2280 through 2283 of Title 13), with the exception of the sulfur content or other properties previously identified by the applicant and approved by the Executive Officer. The Executive Officer may approve test fuel(s) that do not comply with Sections 2280 through 2283 of Title 13 of the California Code of Regulations if the fuel(s) are

determined to be, based on sound science and engineering, representative of commercially available fuel typically used for the intended application(s).

(2) If operation or performance of a diesel emission control strategy is affected by fuel sulfur content, the sulfur content of the test fuel must be no less than 66 percent of the stated maximum sulfur content for the diesel emission control strategy, unless
   (A) the testing is performed with fuel containing 15 ppmw or less sulfur for verification on 15 ppmw or less sulfur diesel fuel, or
   (B) the testing is performed with diesel fuel commercially available in California for verification on CARB diesel fuel (i.e., fuel meeting the specifications in Title 13, California Code of Regulations, Sections 2280 through 2283).

(3) Baseline testing may be conducted with commercially available diesel fuel or diesel fuel with 15 ppmw or less sulfur. Baseline and control tests must be performed using the same fuel unless the control fuel is specified as a component of the emission control strategy.

(4) The test fuel (or batch of fuel purchased) must be analyzed using American Society for Testing and Materials (ASTM) test methods listed in Table 6 (See Section 2710), which are incorporated herein by reference. At a minimum, sulfur content, aromatic content, polycyclic aromatic hydrocarbons, nitrogen content, and cetane number must be reported. The Executive Officer may ask for additional properties to be reported if evidence suggests those properties may affect functioning of the diesel emission control strategy.

(e) Test Cycle. The diesel emission control strategy must be tested using the test cycles indicated in subparagraphs 1-3 below (summarized in Table 2) or with an alternative cycle(s) approved by the Executive Officer pursuant to subsection (f) below. The Executive Officer may require the applicant to conduct additional testing if such information is necessary for a complete evaluation of the control technology.

Table 2. Test Cycles for Emission Reduction Testing*

Test Type	On-Road	Off-Road (including portable engines)	Stationary
Engine	FTP Heavy-duty Transient Cycle (1 cold-start and 3 hot-starts)	Steady-state test cycle from ARB off-road regulations until December 31, 2008 with Executive Officer approval, otherwise; Transient test cycle from ARB off-road regulations (3 hot-starts either cycle)	Discrete mode test cycle from ARB off-road regulations (3 hot-starts)
Chassis	UDDS (3 hot-starts) and a low-speed test cycle per 2703 (e)(1)(B)2. (3 hot-starts).	Not Applicable	Not Applicable

FTP = Federal Test Procedure; UDDS = Urban Dynamometer Driving Schedule

(1) On-road Engines and Vehicles. For on-road diesel-fueled vehicles, the applicant may choose between engine dynamometer testing and chassis dynamometer testing, subject to the following conditions. Engine testing may be used for verification of an absolute engine emissions level or a percent emission reduction. Chassis testing may be used only to verify a percent emission reduction. The applicant may use emission test data to satisfy the durability test data requirement, but must follow the same testing option for the remaining durability tests (see Section 2704).

(A) Engine testing must consist of one cold-start and at least three hot-start tests using the Federal Test Procedure (FTP) Heavy-duty Transient Cycle for engines used in on-road applications, in accordance with the provisions in the Code of Federal Regulations, Title 40, Part 86, Subpart N.

(B) The applicant must conduct all chassis tests in accordance with the provisions of the Code of Federal Regulations, Title 40, Part 86, Subpart N insofar as they pertain to chassis dynamometer testing. Chassis testing must include two separate test cycles as follows:

1. At least three hot-start tests using the Urban Dynamometer Driving Schedule (UDDS) (see Code of Federal Regulations, Title 40, Part 86, appendix I (d)).
2. Three hot-start tests using a low-speed chassis test cycle representing urban stop-and-go traffic operation. The test cycle must include a repetitive series of idling periods immediately

followed by events of maximum vehicle acceleration. The applicant can propose, for Executive Officer approval, a low-speed cycle as applicable to the type of vehicle and vehicle operation for which the diesel emission control strategy is intended. The Executive Officer will provide examples (e.g., New York Bus Cycle) of appropriate test cycles upon request by the applicant during the verification process. The applicant may request that the Executive Officer waive the requirement to conduct the low-speed chassis test. In reviewing this request, the Executive Officer may consider all relevant information including, but not limited to, characteristics of the duty cycles in the emission control group and the principles of operation of the diesel emission control strategy.

3. The driver must follow the test cycles as closely as possible and must not deviate beyond the following tolerances (See Code of Federal Regulation, Part 86, Subpart M, 86.1215-85).
   a. The upper limit is 4 miles per hour higher than the highest point on the trace within 1 second of the given time.
   b. The lower limit is 4 miles per hour lower than the lowest point on the trace within 1 second of the given time.
   c. Speed variations greater than the tolerances (such as may occur during gear changes or braking spikes) are acceptable, provided they occur for less than 2 seconds on any occasion and are clearly documented as to the time and speed at that point of the test cycle.
   d. Speeds lower than those prescribed are acceptable, provided the vehicle is operated at maximum available power during such occurrences.

(C) For any diesel emission control strategy intended to reduce NOx from on-road applications, the applicant must identify and discuss the effects of elevated NOx emissions on the diesel emission control strategy (emissions of NOx that are significantly greater than certified levels are said to be elevated, and may result, for example, from the activation of an AECD that advances fuel injection timing under cruise conditions). The applicant's discussion must include effects on emission reduction performance, durability, and safety considerations, how the strategy would respond to elevated NOx emissions that do not occur at the time the strategy is calibrated, and must be supported by engineering justification and any pertinent data.

(2) Off-road Engines and Equipment (including portable engines). For off-road diesel-fueled vehicles and equipment, the applicant must follow the transient test procedures outlined in the ARB off-road regulations (California Code of Regulations, Title 13, Section 2423 and the incorporated California Exhaust Emissions Standards and Test Procedures for New 2008 and Later Tier 4 Off-Road Compression-Ignition Engines, Part I-C). For all variable speed engines, a minimum of three

hot-start tests must be conducted using the Nonroad Transient Composite Cycle (NRTC).

(A) The Executive Officer may require the applicant to follow another test cycle if the Executive Officer determines that it is more representative of the in-use duty cycle of the off-road application for which the applicant seeks verification.

(B) An applicant may follow the steady state test procedure outlined in the ARB off-road regulations (California Code of Regulations, Title 13, Section 2423 and the incorporated California Exhaust Emission Standards and Test Procedures for New 2000 and Later Tier 1, Tier 2, and Tier 3 Off-Road Compression-Ignition Engines, Part I-B) only if the applicant has submitted a complete preliminary verification application by October 1, 2008 and has received a letter of notification from the Executive Officer, dated no later than December 31, 2008 that the application is complete. In addition, the applicant must submit a complete final verification application that is consistent with the terms of the approved preliminary verification application by July 1, 2010. If the applicant fails to submit a complete final verification application by July 1, 2010, the applicant must test using the NRTC.

(C) An applicant with a system verified after October 19, 2007 using the steady state test procedure outlined in the ARB off-road regulations (California Code of Regulations, Title 13, Section 2423 and the incorporated California Exhaust Emission Standards and Test Procedures for New 2000 and Later Tier 1, Tier 2, And Tier 3 Off-Road Compression-Ignition Engines, Part I-B) must submit emissions test data using the NRTC by January 1, 2013. The Executive Officer will reassess and potentially revise the verification status of the system, claimed emissions reductions, and compliance with NO_2 emissions requirements based on the submitted data. Appropriate testing must include a pre-conditioned unit, an aged unit, and a baseline test. If such data are not received and approved by the Executive Officer by January 1, 2013, the verification will be revoked. A verification awarded prior to October 19, 2007, is not subject to this requirement. A verification for which the Executive Officer determines the NRTC is not appropriate per section 2703(e)(2)(A) is not subject to this requirement.

(D) Applicants may request that the Executive Officer consider alternative test cycles, as described in subsection (f).

(3) Stationary Engines. For stationary engines, the applicant must follow the discrete mode test procedures outlined in the ARB off-road regulations (as referenced in (2) above). A minimum of three hot-start tests must be conducted using the specified test cycle. Applicants may request that the Executive Officer consider alternative test cycles and methods, as described in subsection (f).

(f) Alternative Test Cycles and Methods. The applicant may request the Executive Officer to approve an alternative test cycle or method in place of a required test cycle or method. In reviewing this request, the Executive Officer will consider all relevant information including, but not limited to, the following:
(1) Test procedures specified in airborne toxic control measures adopted by the ARB, e.g. the Airborne Toxic Control Measure for Stationary Compression Ignition Engines,
(2) Similarity of average speed, percent of time at idle, average acceleration, and other characteristics to the specified test cycle or method and in-use duty cycle,
(3) Body of existing test data generated using the alternative test cycle or method,
(4) Technological necessity, and
(5) Technical ability to conduct the required test.

(g) Test Run. The number of tests indicated in Table 2 must be run for both baseline (without the diesel emission control strategy implemented) and control configurations. For strategies that include exhaust aftertreatment, engine backpressure and exhaust temperature must be measured and recorded on a second-by-second basis (1 Hertz) during at least one baseline run and each of the control test runs. For strategies that use a chemical reductant to reduce emissions of NOx from on-road or off-road applications, the amount of reductant consumed during each control test run must be measured and recorded.

(h) Emissions During Particulate Filter Regeneration Events. For any diesel emission control strategy that has a distinct regeneration event, emissions that occur during the event must be measured and taken into account when determining the net emission reduction efficiency of the system. If a regeneration event will not occur during emission testing, applicants may pre-load the diesel emission control system with diesel PM to force such an event to occur during testing, subject to the approval of the Executive Officer. Applicants must provide data or engineering analysis indicating when events occur on test cycles and in actual operation (e.g., backpressure data).

(i) Results. For all valid emission tests used to support emission reduction claims, the applicant must report emissions of total PM, non-methane hydrocarbons or total hydrocarbons (whichever is used for the relevant engine or vehicle certification), oxides of nitrogen, nitrogen dioxide, carbon monoxide, and carbon dioxide.
(1) For mobile sources, or for engines tested using an engine dynamometer, emissions must be reported in grams/mile (g/mile) or grams/brake horsepower-hour (g/bhp-hr).
(2) For stationary engines, gaseous and particulate matter emissions must be reported as required by the test methods approved by the Executive Officer.

(j) Incomplete and Aborted Tests. The applicant must identify all incomplete and aborted tests and explain why those tests were incomplete or aborted.

(k) Additional Analyses. The Executive Officer may require the applicant to perform additional analyses if there is reason to believe that the use of a diesel emission control strategy may result in the increase of toxic air contaminants, other harmful compounds, or a change in the nature or amount of the emitted particulate matter.
  (1) In its determination, the Executive Officer may consider all relevant data, including but not limited to the following:
    (A) The addition of any substance to the fuel, intake air, or exhaust stream,
    (B) Whether a catalytic reaction is known or reasonably suspected to increase toxic air contaminants or ozone precursors,
    (C) Results from scientific literature,
    (D) Field experience, and
    (E) Any additional data.
  (2) These additional analyses may include, but are not limited to, measurement of the following:
    (A) Benzene
    (B) 1,3-butadiene
    (C) Formaldehyde
    (D) Acetaldehyde
    (E) Polycyclic aromatic hydrocarbons (PAH)
    (F) Nitro-PAH
    (G) Dioxins
    (H) Furans
  (3) The Executive Officer will determine appropriate test methods for additional analyses in consultation with the applicant.

(l) Quality Control of Test Data. The applicant must provide information on the test facility, test procedure, and equipment used in the emission testing. For data gathered using on-road and off-road test cycles and methods, applicants must provide evidence establishing that the test equipment used meets the specifications and calibrations given in the Code of Federal Regulations, Title 40, Part 86, subpart N. The testing information must be approved by the Executive Officer.

(m) The Executive Officer may, with respect to any diesel emission control strategy sold, leased, offered for sale, or manufactured for sale in California, order the applicant or strategy manufacturer to make available for testing and/or inspection a reasonable number of diesel emission control systems, and may direct that they be delivered at the applicant's expense to the state board at the Haagen-Smit Laboratory, 9528 Telstar Avenue, El Monte, California or where specified by the Executive Officer. The Executive Officer

may also, with respect to any diesel emission control strategy being sold, leased, offered for sale, or manufactured for sale in California, have an applicant test and/or inspect a reasonable number of units at the applicant or manufacturer's facility or at any test laboratory under the supervision of the Executive Officer.

NOTE: Authority cited: Sections 39002, 39003, 39500, 39600, 39601, 39650-39675, 40000, 43000, 43000.5, 43011, 43013, 43018, 43105, 43600 and 43700, Health and Safety Code. Reference: Sections 39650-39675, 43000, 43009.5, 43013, 43018, 43101, 43104, 43105, 43106, 43107 and 43204-43205.5 Health and Safety Code; Title 17 California Code of Regulations Section 93000.

§ 2704. Durability Testing Requirements

(a) The applicant must demonstrate, to the satisfaction of the Executive Officer, the durability of the applicant's diesel emission control strategy through an actual field or laboratory-based demonstration combined with chassis or engine dynamometer-based emission tests. If the applicant chooses a laboratory-based durability demonstration, an additional field demonstration will be required to demonstrate in-field compatibility (pursuant to Section 2705). If the applicant has demonstrated the durability of the identical system in a prior verification or has demonstrated durability through field experience, the applicant may request that the Executive Officer accept the previous demonstration in fulfillment of this requirement. In evaluating such a request, the Executive Officer may consider all relevant information including, but not limited to, the similarity of baseline emissions and application duty cycles, the relationship between the emission control group used in previous testing and the current emission control group, the number of engines tested, evidence of successful operation and user acceptance, and published reports.

(b) Engine Selection. Subject to the approval of the Executive Officer, the applicant may choose the engine and application to be used in the durability demonstration. The engine and application must be representative of the emission control group for which verification is sought. The selected engine need not be the same as the engine used for emission testing, but if the applicant does use the same engine, the emission testing may also be used for the initial durability tests. Emissions of NO_2 from the emissions test engine must not exceed 15 percent of the total baseline NOx emissions by mass. If there is a special category of engines with NO_2 emission levels that normally exceed 15 percent, this requirement may be adjusted for those engines at the discretion of the Executive Officer.

(c) Test Fuel.
(1) The test fuel must meet the specifications in the California Code of Regulations (Sections 2280 through 2283 of Title 13), with the exception

of the sulfur content or other properties previously identified by the applicant and approved by the Executive Officer. The Executive Officer may approve test fuel(s) that do not comply with Sections 2280 through 2283 of Title 13 of the California Code of Regulations if the fuel(s) are determined to be, based on sound science and engineering, representative of commercially available fuel typically used for the intended application(s).

(2) If operation or performance of a diesel emission control strategy is affected by fuel sulfur content, the sulfur content of the test fuel must be no less than 66 percent of the stated maximum sulfur content for the diesel emission control strategy, unless
   (A) the testing is performed with fuel containing 15 ppmw or less sulfur for verification on 15 ppmw or less sulfur diesel fuel, or
   (B) the testing is performed with diesel fuel commercially available in California for verification on CARB diesel fuel (i.e., fuel meeting the specifications in Title 13, California Code of Regulations, Sections 2280 through 2283).

(3) Baseline testing may be conducted with commercially available diesel fuel or diesel fuel with 15 ppmw or less sulfur. Baseline and control tests must be performed using the same fuel unless the control fuel is specified as a component of the emission control strategy.

(4) The test fuel (or batch of fuel purchased) must be analyzed using American Society for Testing and Materials (ASTM) test methods listed in Table 6 (See Section 2710), which are incorporated herein by reference. At a minimum, sulfur content, aromatic content, polycyclic aromatic hydrocarbons, nitrogen content, and cetane number must be reported. The Executive Officer may ask for additional properties to be reported if evidence suggests those properties may affect functioning of the diesel emission control strategy.

(d) Service Accumulation. The durability demonstration consists of an extended service accumulation period in which the diesel emission control strategy is implemented in the field or in a laboratory accepted by the Executive Officer, with emission reduction testing before and after the service accumulation. Service accumulation begins after the first emission test and concludes before the final emission test. The pre-conditioning period required in Section 2703 (c) cannot be used to meet the service accumulation requirements.

(1) Minimum Durability Demonstration Periods. The minimum durability demonstration periods are shown in Table 3, below.

Table 3. Minimum Durability Demonstration Periods

Engine Type	Minimum Durability Demonstration Period
On-Road	50,000 miles or 1000 hours
Off-Road (including portable engines) and Stationary	1000 hours
Stationary Emergency Standby Engines	500 hours

(2) Temperature and Backpressure Measurement Requirements. For strategies that include exhaust aftertreatment, engine backpressure and exhaust temperature must be measured and recorded for 1000 hours or over the entire durability period (whichever is shorter). The applicant must propose a measurement and recording protocol for approval by the Executive Officer. The protocol may include, but is not limited to, measurement and recording of values once every few seconds, or higher frequency measurement with recording of averages, minima, and maxima over longer time intervals. Data must be submitted electronically in columns as a text file or another format approved by the Executive Officer.

(3) NOx Emissions Measurement Requirements. For strategies that include exhaust aftertreatment to reduce emissions of NOx, the mass emissions of NOx both upstream and downstream of the aftertreatment device must be measured and recorded for at least the first and last 100 hours of the durability period. The applicant must propose a measurement method for approval by the Executive Officer. The method may include, but is not limited to, the use of NOx sensors before and after the device. Measurements of NOx emissions must occur on at least a 1 Hertz basis. Data must be recorded as averages over time intervals no greater than 10 seconds. Data must be submitted electronically in columns as a text file or another format approved by the Executive Officer.

(4) Fuel for Durability Demonstrations. The fuel used during durability demonstrations should be equivalent to the test fuel, or a fuel with properties less favorable to the durability of the emission control strategy. Durability demonstrations may, at the applicant's option and with the Executive Officer’s approval, include intentional misfueling events so that data on the effects of misfueling may be obtained.

(e) Third-Party Statement for In-field Durability Demonstrations. For in-field durability demonstrations, the applicant must provide a written statement from

an Executive Officer approved third party, such as the owner or operator of the vehicle or equipment used, at the end of the durability period. The statement must describe overall performance, maintenance required, problems encountered, and any other relevant comments. The results of a visual inspection conducted by the third party at the end of the demonstration period must also be described. The description should comment on whether the diesel emission control strategy is physically intact, securely mounted, leaking any fluids, and should include any other evaluative observations.

(f) Test Cycle. Testing requirements are summarized in Table 4. Note that the same cycle(s) must be used for both the initial and final tests.
(1) On-Road Applications. The applicant must perform either chassis or engine dynamometer-based testing before beginning and after completion of the service accumulation as specified in Table 4. A minimum of three hot-start tests are required for chassis testing while a minimum of one cold-start and three hot-start tests are required for engine testing. Chassis testing requires an additional three hot-starts on a low-speed cycle as described in Section 2703(e)(1)(B)2. As indicated in Section 2703(e)(1)(B)2., the applicant may request the Executive Officer to waive the tests on a low-speed cycle. If a field durability demonstration is selected, the applicant must perform chassis dynamometer testing, or request that the Executive Officer consider engine dynamometer testing. In reviewing the request, the Executive Officer may consider all relevant information, including, but not limited to the following:
(A) Similarity of the field vehicle's engine to the laboratory engine, and
(B) Similarity of the diesel emission control system's calibration and set-up when installed on the field vehicle to that when installed on the laboratory engine.
(2) Off-road and Stationary Applications. The applicant must use the same cycle for the emission reduction testing as defined in Section 2703. A minimum of three hot-start tests is required.

(g) Test Run. The requirements for emissions reduction testing are summarized in Table 4, below. Note that special pre-conditioning requirements may apply. See section 2706(a)(4) for details.
(1) The diesel emission control strategy must undergo one set of emission tests before beginning and after completion of the service accumulation. Baseline testing with test repetitions as indicated in Table 4 must be conducted before and after the service accumulation. If baseline testing after the service accumulation is not technically feasible, the applicant may request the Executive Officer to waive the requirement. If there are substantial test data from previous field studies or field demonstrations, applicants may request that the Executive Officer consider these in place of the initial emission tests.
(2) As an alternative to testing a single unit before and after the service accumulation period, the applicant may request that the Executive Officer

consider the testing of two identical units, one that has been pre-conditioned and another that has completed the service accumulation period. In reviewing the request, the Executive Officer may consider all relevant information, including, but not limited to, the following:

(A) The effect of the diesel emission control strategy on engine operation over time. Strategies that cause changes in engine operation are likely not to qualify for this testing option.

(B) The quality of the evidence the applicant can provide to support that the two units are identical,

(C) Previous experience with similar or related technologies, and

(D) Whether the applicant is participating in the U.S. EPA verification process and has made an agreement with U.S. EPA to test two units.

(3) For strategies that include exhaust aftertreatment, engine backpressure and exhaust temperature must be measured and recorded on a second-by-second basis (1 Hertz) during at least one baseline run and each of the control test runs.

(4) For strategies that use a chemical reductant to reduce emissions of NOx from on-road or off-road applications, the amount of reductant consumed during each control test run must be measured and recorded.

Table 4. Emission Tests Required for Durability Demonstrations

Application	Test Type	Initial Test (prior to service accumulation) Final Test (after completion of 100% of the service accumulation)
On-Road	Engine	FTP Heavy-duty Transient Cycle (1 cold and 3 hot-starts)
	Chassis	UDDS (3 hot-starts) and a low-speed cycle per 2703 (e)(1)(B)2.(3 hot-starts)
Off-Road and portable engines	Engine	Steady-state test cycle from ARB off-road regulations or an alternative cycle (3 hot-starts)
Stationary	Engine	Steady-state test cycle from ARB off-road regulations or an alternative cycle (3 hot-starts)

(h) Maintenance During Durability Demonstration. Except for emergency engine repair, only scheduled maintenance on the engine and diesel emission control system and re-fill of additives (if any) may be performed during the durability

demonstration. If normal maintenance includes replacement of any component of the diesel emission control system, the time (miles, years, or hours) between component change or refill must be reported with the results of the demonstration.

(i) Functional Testing of Monitoring and Notification Systems. The applicant must demonstrate the durability of all monitoring and notification systems employed by the diesel emission control strategy. Such systems include, but are not limited to, backpressure monitors, reductant level monitors, malfunction indicator systems, and mechanisms to de-rate an engine's maximum power output. The applicant must propose test procedures to demonstrate the durability of the monitoring and notification systems on a diesel emission control strategy that has completed the service accumulation period.

(j) Performance Requirements. The diesel emission control strategy must meet the following requirements throughout the durability demonstration period:
(1) If the applicant claims a percent emission reduction, the percent emission reduction must meet or exceed the initial verified percent emission reduction level.
(2) If the applicant claims to achieve 0.01 g/bhp-hr for PM, the PM emission level must not exceed 0.01 g/bhp-hr.
(3) The diesel emission control system must maintain its physical integrity. Its physical structure and all of its components not specified for regular replacement during the durability demonstration period must remain intact and fully functional.
(4) The diesel emission control strategy must not cause any damage to the engine, vehicle, or equipment.
(5) The backpressure caused by the diesel emission control strategy should not exceed the engine manufacturer's specified limits, or must not result in any damage to the engine.
(6) No maintenance of the diesel emission control system beyond that specified in its owner's manual will be allowed without prior Executive Officer approval.

(k) Conditional Verification for Off-road and Stationary Applications. If the Executive Officer determines that the diesel emission control strategy is technologically sound and appropriate for the intended application, he may grant a conditional verification for off-road and stationary applications upon completion of 33 percent of the minimum durability period. In making this determination, the Executive Officer may consider all relevant information including, but not limited to, the following: the design of the diesel emission control system, filter and catalyst substrates used, similarity of the system under consideration to verified systems, the intended application of the diesel emission control system, other relevant testing data, and field experience. Where conditional verification is granted, full verification must be obtained by completing the durability testing and all other remaining requirements. These

requirements must be completed within a year after receiving conditional verification. For the aforementioned time period, conditional verification is equivalent to verification for the purposes of satisfying the requirements of in-use emission control regulations.

(l) Failure During the Durability Demonstration Period. If the diesel emission control strategy fails to maintain its initial verified percent emission reduction or emission level for any reason, the Executive Officer may downgrade the strategy to the verification level which corresponds to the lowest degraded performance observed in the durability demonstration period. If the diesel emission control strategy fails to maintain at least a 25 percent PM reduction or 25 percent NOx reduction at any time during the durability period, the diesel emission control strategy will not be verified. If the diesel emission control strategy fails in the course of the durability demonstration period, the applicant must submit a report explaining the circumstances of the failure within 90 days of the failure. The Executive Officer may then determine whether to deny verification or allow the applicant to correct the failed diesel emission control strategy and either continue the durability demonstration or begin a new durability demonstration.

NOTE: Authority cited: Sections 39002, 39003, 39500, 39600, 39601, 39650-39675, 40000, 43000, 43000.5, 43011, 43013, 43018, 43105, 43600 and 43700, Health and Safety Code. Reference: Sections 39650-39675, 43000, 43009.5, 43013, 43018, 43101, 43104, 43105, 43106, 43107 and 43204-43205.5 Health and Safety Code; and Title 17 California Code of Regulations Section 93000.

§ 2705. Field Demonstration Requirements.

(a) The applicant must demonstrate compatibility of its diesel emission control strategy in the field with at least one vehicle or piece of equipment belonging to the initial emission control group for which it seeks verification. Note that if the durability demonstration selected by the applicant is in-field, it may be used to satisfy the field demonstration requirement for that emission control group.

(1) Compatibility is determined by the Executive Officer based on the third-party statement (see part (c) of this section) and any other data submitted including backpressure data. A diesel emission control strategy is compatible with the chosen application if it:

(A) Does not cause damage to the engine or engine malfunction

(B) Does not cause backpressure outside of the engine manufacturer's specified limits or which results in any damage to the engine

(C) Does not hinder or detract from the vehicle or equipment's ability to perform its normal functions

(D) Is physically intact and well mounted with no signs of leakage or other visibly detectable problems

(2) To determine whether additional emission control groups require separate field demonstrations, the Executive Officer may consider all relevant information, including, but not limited to existing field experience and engineering justification and analysis.

(b) Test Period.
(1) For on- and off-road engines, and stationary engines not used in emergency generators, a vehicle or piece of equipment must be operated with the diesel emission control strategy installed for a minimum period of 200 hours or 10,000 miles, whichever occurs first.
(2) For stationary emergency standby engines, the emission control system must remain in the field for at least 30 days and operation must include:
(A) 12 maintenance runs (allowing for engine cool down between runs), and
(B) a minimum of two separate 4 hour sessions where the engine is operated under load (allowing engine cool down between runs).

(c) Reporting Requirements.
(1) Temperature and Backpressure Measurement Requirements. For strategies that include exhaust aftertreatment, engine backpressure and exhaust temperature must be measured and recorded over the entire demonstration period. The applicant must propose a measurement and recording protocol for approval by the Executive Officer. The protocol may include, but is not limited to, measurement and recording of values once every few seconds, or higher frequency measurement with recording of averages, minima, and maxima over longer time intervals. Data must be submitted electronically in columns as a text file or another format approved by the Executive Officer.
(2) NOx Emissions Measurement Requirements. For strategies that include exhaust aftertreatment to reduce emissions of NOx, the mass emissions of NOx both upstream and downstream of the aftertreatment device must be measured and recorded over the entire demonstration period. The applicant must propose a measurement method for approval by the Executive Officer. The method may include, but is not limited to, the use of NOx sensors before and after the device. Measurements of NOx emissions must occur on at least a 1 Hertz basis. Data must be recorded as averages over time intervals no greater than 10 seconds. Data must be submitted electronically in columns as a text file or another format approved by the Executive Officer.
(3) Third Party Statement. The applicant must provide a written statement from a third party approved by the Executive Officer, such as the owner or operator of the vehicle or equipment used in the field demonstration. The written statement must be provided at the end of the test period and must describe the following aspects of the field demonstration: overall performance of the test application and the diesel emission control strategy, maintenance performed, problems encountered, and any other

relevant information. The results of a visual inspection conducted by the third party at the end of the demonstration period must also be described. The description should comment on whether the diesel emission control strategy is physically intact, securely mounted, leaking any fluids, and should include any other evaluative observations.

(d) Failure During the Field Demonstration. If the diesel emission control strategy fails in the course of the field demonstration, the applicant must submit a report explaining the circumstances of the failure within 90 days of the failure. The Executive Officer may then determine whether to deny verification or allow the applicant to correct the failed diesel emission control strategy and either continue the field demonstration or begin a new demonstration.

NOTE: Authority cited: Sections 39002, 39003, 39500, 39600, 39601, 39650-39675, 40000, 43000, 43000.5, 43011, 43013, 43018, 43105, 43600 and 43700, Health and Safety Code. Reference: Sections 39650-39675, 43000, 43009.5, 43013, 43018, 43101, 43104, 43105, 43106, 43107 and 43204-43205.5 Health and Safety Code; and Title 17 California Code of Regulations Section 93000.

§ 2706. Other Requirements.

(a) Limit and Procedure for Measuring Nitrogen Dioxide (NO_2).
(1) In order for a diesel emission control strategy to be verified, effective January 1, 2007, the diesel emission control strategy must not increase emissions of NO_2 by more than an increment equivalent in mass to 30 percent of the baseline NOx emission level. Effective January 1, 2009, the increment is reduced to 20 percent of the baseline NOx emission level. The average of NO_2 emission levels from both the initial and final emissions tests described in Section 2704(g) is used to determine compliance with the NO_2 limit. For chassis dynamometer testing, only the NO_2 emission level over the UDDS cycle is used. The first NO_2 emission limit takes effect beginning on January 1, 2007. Diesel emission control strategies verified and installed prior to January 1, 2007 are exempted from this requirement. Those verified prior to January 1, 2007 will no longer be allowed for installation after January 1, 2007 unless they meet the appropriate NO_2 emission limit. After January 1, 2007, all diesel emission control strategies verified and installed must meet this requirement.
(2) NO_2 emissions are to be quantified by one of the following methods:
(A) Two chemiluminescence analyzers,
(B) A dual-path chemiluminescence analyzer, or
(C) An alternative method approved by the Executive Officer.
(3) Analyzer configuration and determination of NO_2 emission level. For (2)(A) and (2)(B), the analyzers are to be fed from a heated and conditioned sample path. If two chemiluminescence analyzers are

employed, they are to be simultaneously fed from a common heated sample path. One instrument (or path) shall be set to NOx mode, while the second shall be set to nitric oxide (NO) mode. The instrument (or path) set to NOx mode receives a sample that has passed through an NO_2-to-NO converter, and the resultant concentration is designated as total NOx ($NO+NO_2$) in the sample. The instrument (or path) that is set to NO mode receives a sample that has not passed through the converter and quantifies the amount of NO only. The difference between NO and NOx is the amount of NO_2 in the sample. Both NO and NOx signals are recorded by an external data acquisition system at 1 Hertz. Using the average concentrations of NO and NOx over the entire test cycle, the conventional equation for calculating total NOx (Code of Federal Regulations, Title 40, part 86, Subpart N) is then used to generate a gram per mile or g/bhp-hr value for both NO and NOx. The resulting value for NO is then subtracted from that for NOx to determine the gram per mile or g/bhp-hr value for NO_2. The instrument for measuring NO and NOx must be calibrated in accordance with the NOx calibration procedure as described in the Code of Federal Regulations, Title 40, part 86, Subpart N.

(4) Pre-conditioning requirements. If the Executive Officer determines that a diesel emission control system has a propensity to increase emissions of NO_2 and that NO_2 emissions from a diesel emission control system could be affected by the presence of particulate matter or ash (as with a catalyzed diesel particulate filter), the system must be preconditioned according to the following procedure:

(A) Initial test (prior to service accumulation). Before conducting the initial emissions test, the unit being tested must be pre-conditioned as follows:

1. Install a new, unused unit on an engine that is an appropriate size for the unit, in a good state of maintenance, and certified to a PM standard equal to or more stringent than that of the engines in the emission control group for which the applicant seeks verification.
2. Operate the engine on one of the test cycles specified below for 25 to 30 hours. For on-road verifications, use either the FTP (hot-start) or UDDS cycle as identified in 2703(e), or the 13-mode Supplemental Emissions Test (SET) in the Code of Federal Regulations, Title 40, Part 86. For off-road and stationary verifications, use either the steady-state test cycle or the Nonroad Composite Transient Cycle (NRTC) (California Code of Regulations, Title 13, Section 2423 and the incorporated California Exhaust Emissions Standards and Test Procedures for New 2008 and Later Tier 4 Off-Road Compression-Ignition Engines, Part I-C) from ARB off-road regulations. For up to 10 hours of the 25 to 30 hour period, beginning after at least the first three test cycle repetitions or ending before at least the last three test cycle repetitions, an applicant may alternatively:

a. Run the engine at high load such that the exhaust temperature is between 350 and 450 degrees Celsius, or
b. Alternate back and forth between high and low loads such that the exhaust temperature never exceeds 525 degrees Celsius and the low load operation does not result in significant soot accumulation at the end of the pre-conditioning period.

3. Measure and record the backpressure and exhaust temperature on a second-by-second basis (1 Hertz) for the duration of the 25 to 30 hour pre-conditioning period. Determine the average backpressure for at least the first three and last three test cycle repetitions.
4. Following the 25 to 30 hour period of operation, remove the unit from the pre-conditioning engine and install it on the emissions test engine, if applicable. Proceed with the initial emissions test and determine NO_2^i, as defined in section 2706(a)(5). Determine the average backpressure over each of the emissions test repetitions and then average those values. The resulting average backpressure is compared with that of the aged unit per subsection (B), below.

(B) Final test (after the service accumulation). Before conducting the final emissions test, the aged unit may need to be pre-conditioned if the backpressure is too high. The applicant may either first perform the backpressure check described below or directly proceed with the final emissions test with the understanding that the test must be repeated if the backpressure is too high.

1. Backpressure check. Run one hot-start of the emissions test cycle with the aged unit installed on the emissions test engine. If using a chassis dynamometer, run the UDDS. Measure and record the backpressure on a second-by-second basis (1 Hertz) and determine the average. No pollutant measurements are necessary. Proceed with the emissions test as described in subsection (B)(3.) below if either the average backpressure is within 30 percent of the average backpressure recorded for the initial test unit or, for transient test cycles, the backpressure does not exceed 60 inches of water for more than two percent of the time, or, for steady-state test cycles, the backpressure never exceeds 60 inches of water. Otherwise, pre-condition the aged unit as described in subsection (B)(2.) below.
2. If the backpressure of the aged unit does not comply with the appropriate criterion described in subsection (B)(1.) above, burn off excess soot or clean out excess ash as necessary. Run an additional repetition of the emissions test cycle (hot-start) to check if the unit complies with the backpressure criterion. Repeat as necessary.
3. Conduct emissions testing with the aged unit. Determine NO_2^f, as defined in section 2706(a)(5.). If the backpressure does not comply with the appropriate criterion described in subsection (B)(1.) above,

pre-condition the unit in accordance with subsection (B)(2.) and retest. If the backpressure check in subsection (B)(1.) was conducted prior to emissions testing and the unit was brought into compliance at that time, do not retest.

(C) In-use compliance testing. Before conducting the first phase of in-use compliance emissions testing, the test units may need to be pre-conditioned. Using the required test cycle, measure and record the backpressure on a second-by-second basis (1 Hertz) over one hot-start test with a cleaned (or pre-conditioned per subsection (A) above) reference unit installed on the engine to be used for in-use compliance testing. The reference unit must be identical to the test units. Measure and record the backpressure of the test units retrieved from the field using the same engine and test cycle (one hot-start) as used with the reference unit. If the backpressure of a given test unit is either within 30 percent of the average backpressure recorded for the reference unit or, for transient test cycles, the backpressure does not exceed 60 inches of water for more than two percent of the time, or, for steady-state test cycles, the backpressure never exceeds 60 inches of water, it does not require pre-conditioning. Otherwise, the test units must be pre-conditioned following subsection (B) above. Other units may not be substituted for the selected test units.

(D) Determination of backpressure. The applicant must submit the actual recorded backpressure in an electronic format as measured on a second-by-second basis over each test run and over the 25 to 30 hour pre-conditioning period. Prior to calculating the average backpressure over a given test run, however, any negative values caused by the draw of the dilution tunnel must first be zeroed.

(5) Determination of compliance with the NO_2 limit. Compliance with the NO_2 limit is based on the average incremental increase in NO_2 emissions as determined by the following equation:

$$\text{Percent Increase} = 100\% \times 0.5 \times [(NO_2^{i} - NO_2^{b}) + (NO_2^{f} - NO_2^{b})] / NOx^{b}$$

Where "NO_2" and "NOx" stand for the mass-based emission rates of NO_2 and NOx, respectively, as determined in subsection (a)(3) above, and the superscripts "i", "f", and "b" stand for "initial test", "final test", and "baseline test", respectively. For in-use compliance testing, the equation is:

$$\text{Percent Increase} = 100\% \times (NO_2^{c} - NO_2^{b}) / NOx^{b}$$

Where the superscript "c" stands for the in-use compliance emissions testing conducted with the unit installed on the test engine.

(6) Alternative Method to Measure NO_2. The applicant may request the Executive Officer to approve an alternative method in place of the required

methods. In reviewing this request, the Executive Officer may consider all relevant information including, but not limited to, the following:
(A) Correlation of the alternative method with the methods stated in 2(A) or 2(B).
(B) Body of existing data generated using the alternative method.

(b) Limits on Other Pollutants.
(1) Limits on non-methane hydrocarbon (NMHC) and NOx. In order for a diesel emission control strategy to be verified, the applicant must comply with one of the following:
(A)The diesel emission control strategy must not increase the emissions of either NMHC or NOx by more than ten percent of the baseline emissions level as reported under section 2708 (a), or
(B)For strategies verified prior to July 1, 2006, the applicant must provide sufficient evidence to demonstrate that the sum of NMHC and NOx emissions with the strategy implemented does not exceed the baseline emission level sum of NMHC and NOx as reported under Section 2708 (a); or
(C) For strategies verified on or after July 1, 2006, the applicant must provide atmospheric modeling data which indicates that widespread use of the strategy will not result in an increase in exposure of the public to ozone. The atmospheric model employed must be approved in advance by the Executive Officer.
(2) Limit on CO.
(A) On-road and Off-road (including portable) Engines. In order for a diesel emission control strategy to be verified, the diesel emission control strategy must not increase the emissions of CO greater than the current CO emission standards for new diesel engines adopted by the Air Resources Board and in effect at the time of verification.
(B) Stationary Engines. In order for a diesel emission control strategy to be verified, the diesel emission control strategy must either:
1. Meet the applicable CO standard for off-road engines of the same model year and maximum rated power as specified in the Off-Road Compression-Ignition Engine Standards (title 13, CCR, section 2423). If no standards have been established for an off-road engine of the same model year and maximum rated power as the stationary diesel-fueled CI engine, then the stationary diesel-fueled CI engine shall meet the Tier 1 standard in title 13, CCR, section 2423 for an off-road engine of the same maximum rated power, irrespective of the stationary diesel-fueled CI engine's model; Or
2. Not increase the emissions of CO by more than 10 percent of the baseline emissions level as reported under Section 2708(a).
(3) Limit on Ammonia (NH_3). In order for a diesel emission control strategy to be verified, the diesel emission control strategy must not increase the emissions of ammonia to a level greater than 25 parts per million by

volume at the tailpipe on average over any test cycle used to support emission reduction claims.

(A) Emissions of ammonia are to be quantified with a method subject to approval by the Executive Officer which employs Fourier Transform Infrared (FTIR) spectroscopy. The applicant may request the Executive Officer to approve an alternative method in place of the required method. In reviewing this request, the Executive Officer may consider all relevant information including, but not limited to, consistency with the method required by U.S. EPA and the body of existing data generated using the alternative method.

(B) If an applicant does not expect its diesel emission control strategy to increase emissions of ammonia, the applicant may request that the Executive Officer waive the requirement to conduct testing for ammonia emissions. In reviewing the request, the Executive Officer may consider all relevant information including, but not limited to, the principles of operation of the diesel emission control strategy, the existence of a mechanism for ammonia formation, and published emissions data from similar technologies.

(C) The strategy must be in compliance with applicable federal, state, and local government requirements relating to ammonia emissions, which may be more stringent than the limit presented here.

(4) Other Pollutants. In order for a diesel emission control strategy to be verified, the diesel emission control strategy must not increase the emissions of other pollutants by more than ten percent of the baseline emission level as reported under Section 2708(a).

(c) Fuel Additives. Diesel emission control strategies that use fuel additives must comply with Section 2710 and meet the following additional requirements for verification. Fuel additives must be used in combination with a level 3 diesel particulate filter unless they can be proven to the satisfaction of the Executive Officer to be safe for use alone. In addition, the applicant must meet the following requirements:

(1) The applicant must submit the exact chemical formulation of the fuel additive,

(2) Diesel emission control systems employing the dosing of an additive in conjunction with a diesel particulate filter must include an on-board monitor of the additive level in the reservoir, integrated with the diesel particulate filter. The on-board monitor for fuel additive must include indicators to notify the operator when the additive level becomes low and when the additive tank is empty. In addition, the on-board monitor must be capable of shutting off the supply of additive, if there is a detected diesel particulate filter problem,

(3) The applicant must submit to the Executive Officer environmental, toxicological, epidemiological, and other health-related data pertaining to the fuel additive every two years. The Executive Officer will review the data, including any new information, and may revoke the verification if the

data indicate that the fuel additives cause, or are linked, to negative environmental, or health consequences.

(4) The applicant must conduct additional emission tests of fuel additives.

(A) Except as provided in (B) below, the additional emission tests must follow the same test procedures, test cycles, and number of test runs as indicated in Section 2703, except that the concentration of the additive must be at least 50 ppm or 10 times higher than that specified for normal use, whichever is highest. In all other respects, the additive in the high concentration test solutions must be identical to that in the fuel additive submitted for verification.

(B) The applicant may petition to use a concentration less than that required in (A), above, if the higher dose would result in catastrophic damage to the engine. The applicant must supply information on the failure modes, and the level of the additive that would trigger failure. The applicant must also supply information and data supporting the highest feasible dose for testing. An increase in emissions is not by itself sufficient to justify a dose lower than that required in (A), above, and must be correlated to potential engine damage. After reviewing this information and any other relevant information, the Executive Officer shall determine if testing at a lower level could be accepted, or if testing must be conducted at 50 ppm or ten times the specified dose rate as required in (A).

(5) Fuel additives must be in compliance with applicable federal, state, and local government requirements. This requirement includes, but is not limited to, registration of fuel additives with the U.S. EPA.

(d) Alternative Diesel Fuels. Alternative diesel fuels must be in compliance with applicable federal, state, and local government requirements. This requirement includes, but is not limited to registration of the alternative diesel fuel with the U.S. EPA. The applicant must conduct additional emission tests of alternative diesel fuels if the Executive Officer determines that such tests are necessary. The Executive Officer may consider all factors including, but not limited to, fuel components that could adversely affect emissions reductions and/or the applications to which they are applied.

(e) Selective Catalytic Reduction (SCR) Systems. A diesel emission control strategy that uses an SCR system to reduce emissions of NO_x has the following additional requirements:

(1) The diesel emission control strategy must include a system to monitor the amount of reductant available and notify the operator when the level is low. The notification must occur and be clearly visible to the operator while the vehicle or equipment is in use.

(2) The diesel emission control strategy must include a strong inducement to ensure that the operator maintains a constant supply of reductant to the SCR system. For example, the diesel emission control strategy may include a mechanism to de-rate the engine's maximum power output if the

operator fails to refill the reductant tank. The inducement must be both resistant to tampering and strong enough to ensure an uninterrupted supply of reductant. The applicant must propose an inducement for approval by the Executive Officer.

(3) The diesel emission control strategy must include a means to ensure that the reductant present in the tank meets the specifications necessary for the SCR system to function properly. The applicant must propose a quality control strategy for approval by the Executive Officer.

(f) Engine Backpressure and Monitoring. During the emission and durability testing, the applicant must demonstrate that the backpressure caused by its diesel emission control system is within the engine manufacturer's specified limits, or will not result in any damage to the engine. Furthermore,

(1) If operation of the engine with the diesel emission control system installed will result in a gradual build-up of backpressure exceeding the engine's specified limits over time (such as due to the accumulation of ash in a filter), information describing how the backpressure will be reduced must be included.

(2) All filter-based diesel emission control systems must be installed with a backpressure monitor to notify the operator when the high backpressure limit, as specified by the engine manufacturer or included in the verification, is approached. The notification must occur and be clearly visible to the operator while the vehicle or equipment is in use. The applicant must identify the high backpressure limits of the system in its application for verification.

(3) The Executive Officer reserves the right to require monitors that identify low backpressure limits in those cases where failures leading to low backpressure are unlikely to be detected, or have the potential to cause environmental damage beyond that caused by the engine prior to being equipped with the emission control strategy (e.g., systems that introduce additives into the fuel).

(g) Fuel and Oil Requirements. The applicant must specify the fuel and lubricating oil requirements necessary for proper functioning of the diesel emission control system. The applicant must also specify any consequences that will be caused by failure to comply with these requirements, as well as methods for reversing any negative consequences.

(h) Maintenance Requirements. The applicant must identify all normal maintenance requirements for the diesel emission control system. The applicant must specify the recommended intervals for cleaning and/or replacing components. Any components to be replaced within the defects warranty period must be covered with the original diesel emission control system package or provided free of charge to the customer at the appropriate maintenance intervals. Any normal maintenance items that the applicant does not intend to provide free of charge must be approved by the Executive

Officer (the applicant is not required to submit cost information for these items). In addition, the applicant must specify procedures for proper handling of spent components and/or materials cleaned from the diesel emission control system. If any such materials are hazardous, the applicant must identify them as such in the owner's manual. For filter-based diesel emission control strategies, the applicant must include procedures for resetting any backpressure monitors after maintenance procedures are completed.

(i) Component Swapping and Re-Designation Practices

(1) End User Device Component Swapping Practices. Applicants may authorize end users to move components of their verified control systems from the original installed configuration and transfer them on to other vehicles or equipment, but only within a common ownership fleet, provided the following provisions are met:

(A) Applicants must first receive written approval outlining the specific component eligible to be moved from the Executive Officer prior to approving any transfers.

(B) Recipient vehicle must be fitted with the same DECS.

(C) Component swapping must also comply with the requirements as described in subsection (i)(3).

(D) Donor vehicle/engine whose component has been moved must remain in compliance with the terms and conditions of the applicable Executive Order and have all DECS components present and functional.

(2) Device Re-Designation Practices. Applicants may authorize end users to completely remove their verified control systems from the original installed configuration and install them on other vehicles or equipment within the end user's commonly owned fleet, provided the following provisions are met:

(A) Applicants must receive written approval from the Executive Officer prior to approving a DECS re-designation.

(B) Any party which removes a verified DECS from an engine/application must remove the verified DECS engine label. If the engine label cannot be removed whole, it must be destroyed.

(C) Any party which re-designates a device to another engine/application which was never previously retrofit with that exact DECS must obtain and properly install an appropriate DECS engine label.

(D) Any party which removes a verified DECS from an engine/application must ensure the engine/application returns to its original factory configuration.

(E) DECS which are more than 10 years old based on the month and date of manufacture listed on the device label, or devices of unknown age, are not legal candidate systems for re-designation to a new engine/application.

(F) DECS system re-designation must also comply with the requirements as described in subsection (i)(3)

(3) Additional Component Swapping and Re-designation Requirements. In addition to the specific requirements in subparts (1) and (2), the following requirements must be met prior to the approval of a component swap or device re-designation:
(A) Applicants must provide written information on approved practices and, compliance with warranty and in-use compliance,
(B) Applicants must provide instructions for assessing if the system still meets its verified emissions reductions (for PM and/or NOx), instructions for device movement to prevent installation on an inappropriate vehicle, and other information required by the EO to assess the request.
(C) The end user must verify that the new recipient vehicle is within the scope of the original verification.
(D) Applicants must specify acceptable end user installation and reinstallation practices in the owner's manual and the installation manual (see section 2706(l) and 2706(n)) and possible repercussions to the end user if such practices are done in an inappropriate manner. (See section 2706(i)).
(E) The applicant must agree to honor the original warranty and warranty period (see sections 2702 and 2707) and must provide a written statement to the EO confirming continued support of the original warranty.
(4) Any device installed under the device re-designation provisions above must be compliant with the warranty requirements in section 2707 of the verification procedure. However, if the original device warranty has expired, the installer must issue a warranty to guard against potential installation defects for a period of one year from the date of installation (see section 2707). Any transfer of a device by an installer that does not offer this installation warranty will not be considered a valid installation. No party shall advertise, sell, lease, or offer for sale or lease, a used verified DECS.

(j) System Labeling.
(1) The applicant must ensure that identical, legible, and durable labels are affixed on both the diesel emission control system and the engine (or an alternate location approved by the Executive Officer) on which the diesel emission control system is installed except as noted in (3) below. The required labels must identify the name, address, and phone number of the manufacturer, the diesel emission control strategy family name (defined in (2) below) of the installed system, a unique serial number, and the month and year of manufacture. The month and year of manufacture are not required on the label if this information can be readily obtained from the applicant by reference to the serial number. The applicant and installer must ensure that the label is affixed such that it is resistant to tampering and degradation from the conditions of its environment. The applicant and/or installer must ensure that the label is visible after installation. In the event that the original system label is damaged or destroyed by the end-

user, the device manufacturer shall issue a replacement. The replacement label must be identical to the original label with the exception of the words "REPLACEMENT LABEL" which must be included at the bottom line of information. A sample scale drawing of the original and replacement labels must be submitted with the verification application. Unless an alternative is approved by the Executive Officer, the label information must be in the following format:

Name, Address, and Phone Number of Manufacturer
Diesel Emission Control Strategy Family Name
Product Serial Number
ZZ-ZZ (Month and Year of manufacture, e.g., 06-02)
REPLACEMENT LABEL*

* "Replacement Label" to be used only when a replacement of the original label has been issued by the device manufacturer.

(2) Diesel Emission Control Strategy Family Name. Each diesel emission control strategy shall be assigned a family name defined as below:

CA/MMM/YYYY/PM#/N##/APP/XXXXX

CA:	Designates a diesel emission control strategy verified in California
MMM:	Manufacturer code (assigned by the Executive Officer)
YYYY:	Year of verification
PM#:	PM verification level 0, 1, 1+, 2, 2+, 3, or 3+ (e.g., PM3 means a level 3 PM emission control system).
N##:	NOx verified reduction level in percent, if any (e.g., N25 means NOx reduction of 25 percent).
APP:	Verified application which may include a combination of On-road (ON),Off-road (OF),or Stationary (ST)
XXXXX:	Five alphanumeric character code issued by the Executive Officer

(3) The applicant may request that the Executive Officer approve an alternative label format. In reviewing this request, the Executive Officer may consider all relevant information including, but not limited to, the informational content of an alternative label as proposed by the applicant.

(k) Additional Information. The Executive Officer may require the applicant to provide additional information about the diesel emission control strategy or its

implementation when such information is needed to assess environmental impacts associated with its use.

(l) Owner's Manual. The applicant must provide a copy of the diesel emission control system owner's manual, which must clearly specify at least the following information:
(1) Warranty statement including the warranty period over which the applicant is liable for any defects.
(2) Installation procedure and maintenance requirements for the diesel emission control system.
(3) Possible backpressure range imposed on the engine.
(4) Fuel consumption penalty, if any.
(5) Fuel requirements including sulfur limit, if any.
(6) Handling and supply of additives, if any.
(7) Instructions for reading and resetting the backpressure monitor.
(8) Requirements for lubrication oil quality and maximum lubrication oil consumption rate.
(9) Contact information for replacement components and cleaning agents.
(10) Contact information to assist an end-user to determine proper ways to dispose of waste generated by the diesel emission control strategy (e.g., ash accumulated in filter-based systems). At a minimum, the owner's manual should indicate that disposal must be in accordance with all applicable Federal, State and local laws governing waste disposal.
(11) Appropriate methods of removing the diesel emission control system from the original installed configuration and installing the system on a different vehicle or piece of equipment, if such practices are allowed. The applicant must state possible repercussions to the end user if such practices are done in an inappropriate manner. (See section 2706(i))
(12) Parts List.

(m) Noise Level Control. Any diesel emission control system that replaces a muffler must continue to provide at a minimum the same level of exhaust noise attenuation as the muffler with which the vehicle was originally equipped by the vehicle or engine manufacturer. Applicants must ensure that the diesel emission control system complies with all applicable noise limits contained in Part 205, Title 40, Code of Federal Regulations and California Vehicle Code, Sections 27150, 27151 and 27200 through 27207, for the gross vehicle weight rating and year of manufacture of the vehicle for which the diesel emission control strategy is intended. All diesel emission control systems must be in compliance with applicable local government requirements for noise control.

(n) Installation Manual. The applicant must provide a copy of the diesel emission control system installation manual that the applicant intends to provide to installers and/or owners.

(o) Parts List. The applicant must include a list of all of the component parts of the diesel emission control system. All primary components must be listed, including, but not limited to, substrates, electronic control units, sensors, injectors, pumps, blowers, storage tanks, and notification lights. Brackets, fasteners, and wiring need not be included. For each listed component, the applicant must give a description and identification number. The applicant must also clearly specify which parts, if any, are not covered by the warranty. Parts that may be excluded from warranty coverage are subject to approval by the Executive Officer.

(p) Multimedia Assessment for Fuel Strategies. Diesel emission control strategies which rely on fuel changes either through use of additives or through use of alternative diesel fuels must undergo an evaluation of the multimedia effects. No diesel emission control strategy that relies on the use of an additive or an alternative fuel may be verified unless a multimedia evaluation of the additive or alternative fuel has been conducted and the California Environmental Policy Council established by Public Resources Code section 71017 has determined that such use will not cause a significant adverse impact on the public health or the environment, pursuant to Health and Safety Code section 43830.8. No person shall sell, offer for sale, supply or offer for supply an alternative fuel or a diesel fuel in California that contains an additive for use in a verified diesel emission control strategy unless such a multimedia evaluation has been conducted and resulted in a determination that use of the alternative fuel or additive will not cause a significant adverse impact on the public health and the environment. The applicant shall bear the expense of conducting the multimedia assessment.

(q) Sales and Installation. No person or entity shall advertise, sell, lease, supply, offer for sale, represent, or install any device, apparatus, mechanism, or fuel based system as a verified diesel emission control strategy for or on any engine, vehicle or equipment that does not meet the terms and conditions of the strategy's Executive Order. The applicant, distributor, and/or installer must ensure that each verified diesel emission control strategy is supplied, sold, leased, and installed pursuant to the provisions of the Executive Order. Failure to follow the provisions of the Executive Order may result in revocation or suspension of the verification and/or any other remedy available under Part 5, Division 26 of the Health and Safety Code.

(r) Aftertreatment Devices. Any control strategy that is installed on or after January 1, 2010 that includes an aftertreatment device such as a diesel particulate filter, must be designed such that the aftertreatment device can only be installed on the application in one unique direction. Any new aftertreatment device installed in the period between February 19, 2009 and December 31, 2009 must indicate the proper direction of exhaust flow so the end user or installer can clearly see how to properly install the device.

(s) Verification of a diesel emission control strategy by the Air Resources Board does not release the applicant from complying with all other applicable legal requirements.

NOTE: Authority cited: Sections 39002, 39003, 39500, 39600, 39601, 39650-39675, 40000, 43000, 43000.5, 43011, 43013, 43018, 43105, 43600, 43700 and 43830.8, Health and Safety Code. Reference: Sections 39650-39675, 43000, 43009.5, 43013, 43018, 43101, 43104, 43105, 43106, 43107, 43204-43205.5 and 43830.8, Health and Safety Code; Section 71017, Public Resources Code; and Title 17 of Regulations Section 93000.

§ 2707. Warranty Requirements.

(a) (1) Product Warranty.

(A) The applicant must warrant to all owners, for ownership within the warranty period and lessees, for lease contracts within the warranty period, that its verified diesel emission control strategy is free from defects in design, materials, workmanship, or operation of the diesel emission control strategy which cause the diesel emission control strategy to fail to conform to the emission control performance level it was verified to, or to the other requirements of Sections 2700-2706, and 2710 for the minimum periods shown in Table 5, provided the operation of and conditions of use for the vehicle, equipment, engine, and diesel emission control strategy conform with the operation and conditions specified in the ARB's Executive Order.

(B) For each engine type and size listed in Table 5, the minimum defects warranty period is terminated by that listed event which occurs first. The warranty must cover the full repair or replacement cost of the diesel emission control strategy, including parts and labor.

(C)The warranty must also cover the full repair or replacement cost of returning engine components to the condition they were in prior to the failure, including parts and labor, for damage to the engine proximately caused by the verified diesel emission control strategy. Repair or replacement of any warranted part, including the engine must be performed at no charge to the vehicle or engine owner. This includes only those relevant diagnostic expenses in the case in which a warranty claim is valid. The applicant may, at its option, instead pay the fair market value of the engine prior to the time the failure occurs.

(D)The repair or replacement of any warranted part otherwise eligible for warranty coverage may be excluded from such warranty coverage if the diesel emission control strategy, vehicle or engine has been abused, neglected, or improperly maintained, and that such abuse, neglect, or improper maintenance was the direct cause of the need for the repair or replacement of the part.

(E) Failure of the vehicle or engine owner to ensure scheduled maintenance or to keep maintenance records for the vehicle, equipment, engine, or diesel emission control strategy may, but shall not per se, be grounds for disallowing a warranty claim.

(2) Installation Warranty

(A) A person or company who installs a verified diesel emission control strategy must warrant that the installation is free from defects in workmanship or materials which cause the diesel emission control strategy to fail to conform to the emission control performance level it was verified to or the other requirements of sections 2700-2706 for the minimum time periods shown in Table 5.

(B) For each engine type and size listed in Table 5, the minimum defects warranty period is terminated by that listed event whichever occurs first. The extent of the warranty coverage provided by installers must be the same as the warranty provided by the applicant as established in subsection (a)(1) and the same exclusions must apply.

Table 5. Minimum Warranty Periods

Engine Type	Engine Size	Minimum Warranty Period
On-Road	Light heavy-duty, 70 to 170 hp, Gross Vehicle Weight Rating (GVWR) less than 19,500 lbs.	5 years or 60,000 miles
	Medium heavy-duty, 170 to 250 hp, GVWR from 19,500 lbs. to 33,000 lbs.	5 years or 100,000 miles
	Heavy heavy-duty, exceeds 250 hp, GVWR exceeds 33,000 lbs.	5 years or 150,000 miles
	Heavy heavy-duty, exceeds 250 hp, GVWR exceeds 33,000 lbs., and the truck is: 1. Typically driven over 100,000 miles per year, and 2. Has less than 300,000 miles on the odometer at the time of installation.	2 years, unlimited miles
Off-Road (includes portable engines) and Stationary	Under 25 hp, and for constant speed engines rated under 50 hp with rated speeds greater than or equal to 3,000 rpm	3 years or 1,600 hours
	At or above 25 hp and under 50 hp	4 years or 2,600 hours
	At or above 50 hp	5 years or 4,200 hours

(b)(1) Product Warranty Statement. The applicant must furnish a copy of the following statement in the owner's manual. The applicant may include descriptions of circumstances that may result in a denial of warranty coverage, but these descriptions shall not limit warranty coverage in any way.

YOUR WARRANTY RIGHTS AND OBLIGATIONS

(Applicant's name) must warrant the diesel emission control system in the application for which it is sold or leased to be free from defects in design, materials, workmanship, or operation of the diesel emission control system which cause the diesel emission control system to fail to conform to the emission control performance level it was verified to, or to the requirements in the California Code of Regulations, Title 13, Sections 2700 to 2706, and 2710, for the periods of time listed below, provided there has been no abuse, neglect, or improper maintenance of your diesel emission control system, vehicle or equipment, as specified in the owner's manuals. Where a warrantable condition exists, this warranty also covers the engine from damage caused by the diesel emission control system, subject to the same exclusions for abuse, neglect or improper maintenance of your vehicle or equipment. Please review your owner's manual for other warranty information. Your diesel emission control system may include a core part (e.g., particulate filter, diesel oxidation catalyst, selective catalytic reduction converter) as well as hoses, connectors, a back pressure monitor (if applicable), and other emission-related assemblies. Where a warrantable condition exists, (applicant's name) will repair or replace your diesel emission control system at no cost to you including diagnosis, parts, and labor.

WARRANTY COVERAGE:

For a (engine size) engine used in a(n) (type of application) application, the warranty period will be (years or hours or miles of operation) whichever occurs first. If any emission-related part of your diesel emission control system is defective in design, materials, workmanship, or operation of the diesel emission control system thus causing the diesel emission control system to fail to conform to the emission control performance level it was verified to, or to the requirements in the California Code of Regulations, Title 13, Sections 2700 to 2706, and 2710, within the warranty period, as defined above, (Applicant's name) will repair or replace the diesel emission control system, including parts and labor.

In addition, (applicant's name) will replace or repair the engine components to the condition they were in prior to the failure, including parts and labor, for damage to the engine proximately caused by the verified diesel emission control strategy. This also includes those relevant diagnostic expenses in the case in which a warranty claim is valid.

(Applicant‘s name) may, at its option, instead pay the fair market value of the engine prior to the time the failure occurs.

OWNER’S WARRANTY RESPONSIBILITY

As the (vehicle, engine, equipment) owner, you are responsible for performing the required maintenance described in your owner’s manual. (Applicant’s name) recommends that you retain all maintenance records and receipts for maintenance expenses for your vehicle, engine, or equipment, and diesel emission control system. If you do not keep your receipts or fail to perform all scheduled maintenance, (applicant’s name) may have grounds to deny warranty coverage. You are responsible for presenting your vehicle, equipment, or engine, and diesel emission control system to a (applicant’s name) dealer as soon as a problem is detected. The warranty repair or replacement should be completed in a reasonable amount of time, not to exceed 30 days. If a replacement is needed, this may be extended to 90 days should a replacement not be available, but must be performed as soon as a replacement becomes available.

If you have questions regarding your warranty rights and responsibilities, you should contact (Insert chosen applicant’s contact) at 1-800-xxx-xxxx or the California Air Resources Board at 9528 Telstar Avenue, El Monte, California 91731, or (800) 363-7664, or electronic mail: helpline@arb.ca.gov.

(2) Installation Warranty Statement. The installer must furnish the owner with a copy of the following statement.

YOUR WARRANTY RIGHTS AND OBLIGATIONS

(Installer’s name) must warrant that the installation of a diesel emission control system is free from defects in workmanship or materials which cause the diesel emission control system to fail to conform to the emission control performance level it was verified to, or to the requirements in the California Code of Regulations, Title 13, Sections 2700 to 2706. The warranty period and the extent of the warranty coverage provided by (installer’s name) must be the same as the warranty provided by the product manufacturer, and the same exclusions must apply.

OWNER’S WARRANTY RESPONSIBILITY

As the vehicle, engine, or equipment owner, you are responsible for presenting your vehicle, engine, or equipment, and diesel emission control system to (installer’s name) as soon as a problem with the installation is detected.

If you have questions regarding your warranty rights and responsibilities, you should contact (Insert chosen installer’s contact) at 1-800-xxx-xxxx or the California Air Resources Board at 9528 Telstar Avenue, El Monte,

California 91731, or (800) 363-7664, or electronic mail: helpline@arb.ca.gov.

(c) Diesel Emission Control Strategy Warranty Report. The applicant must submit a warranty report to the Executive Officer by April 1 of each calendar year. The applicant must also submit a warranty report within 30 calendar days if warranty claims exceed four percent of the number of diesel engines using the diesel emission control strategy. The warranty report must include the following information:

(1) Annual and cumulative sales, and annual and cumulative leases of diesel emission control systems (California only).

(2) Annual and cumulative production of diesel emission control systems (California only).

(3) Annual summary of warranty claims (California only). The summary must include:

(A) A description of the nature of the claims and of the warranty replacements or repairs. The applicant must categorize warranty claims for each diesel emission control strategy family by the component(s) replaced or repaired.

(B) The number and percentage of diesel emission control systems of each model for which a warranty replacement or repair was identified.

(C) A short description of the diesel emission control system component that was replaced or repaired under warranty and the most likely reason for its failure.

(4) Date the warranty claims were filed and the engine family and application the diesel emission control systems were used with.

(5) Delineate the reason(s) for any instances in which warranty service is not provided to end-users that file warranty claims.

NOTE: Authority cited: Sections 39002, 39003, 39500, 39600, 39601, 39650-39675, 40000, 43000, 43000.5, 43011, 43013, 43018, 43105, 43600 and 43700, Health and Safety Code. Reference: Sections 39650-39675, 43000, 43009.5, 43013, 43018, 43101, 43104, 43105, 43106, 43107, and 43204-43205.5 Health and Safety Code; Title 17 California Code of Regulations Section 93000.

§ 2708. Determination of Emissions Reduction.

(a) Calculation of Emissions Reduction. The emissions reduction verified for a diesel emission control strategy is based on the average of all valid test results before (baseline) and after (control) implementation of the diesel emission control strategy. Test results from both emission testing and durability testing are to be used. If the applicant chooses to perform either the initial or the final durability baseline test, but not both, it must use those results to calculate the reductions obtained in both the initial and final control tests.

(1) Percentage Reduction. The percentage reduction for a given pair of baseline and control test sets (where a "set" consists of all test cycle repetitions, e.g., the test set of 3 hot-start UDDS tests) is the difference between the average baseline and average control emissions divided by the average baseline emissions, multiplied by 100 percent. The average of all such reductions, as shown in the equation below, is used in the verification of a diesel emission control strategy.

$$\text{Percentage Reduction} = 100\% \times \frac{\Sigma\,[(\text{baseline}_{AVG} - \text{control}_{AVG})/\text{baseline}_{AVG}]}{\text{Number of control test sets}}$$

Where:

Σ = sum over all control test sets

baseline_{AVG} or control_{AVG} = average of emissions from all baseline or control test repetitions within a given set

(A) For any test set involving cold and hot starts, the time weighted emission result is to be calculated by weighting the cold-start emissions by one-seventh (1/7) and the hot-start emissions by six-sevenths (6/7) as shown below.

Weighted Emission Result = 1/7* average cold-start emissions + 6/7* average hot-start emissions

(B) For applicants seeking verification of NOx reductions from on-road applications, weighted test results from the additional test set described in subsection 2703(e)1(C) are included in the percentage reduction equation above. The Executive Officer shall determine an appropriate weighting factor in consultation with the applicant based on factors including, but not limited to, the amount of time that vehicles within the selected emission control group have elevated NOx emissions and the breadth of engines and applications encompassed by the emission control group.

(2) The absolute emission level is the average control emission level, as defined in the following equation:

$$\text{Absolute Emission Level} = \frac{\Sigma\,(\text{control}_{AVG})}{\text{Number of control test sets}}$$

(b) Categorization of the Diesel Emission Control Strategy. The Executive Officer shall categorize diesel emission control strategies to reduce PM and NOx emissions based on their verified emission reductions. Diesel emission control strategies that reduce NOx will be assigned their verified emission reduction (Mark 1, 2, 3, 4, or 5) in 15 percent increments starting at 25 percent (See Table 1 in section 2702). Diesel emission control strategies are categorized by their PM reductions as follows:

(1) Level zero: the system has been demonstrated under these procedures to reduce PM emissions by less than 25 percent from the baseline emission level and to reduce NOx emissions by at least 25 percent from the baseline emission level.

(2) Level one: the system has been demonstrated under these procedures to reduce PM emissions by at least 25 percent from the baseline emission level.

(3) Level two: the system has been demonstrated under these procedures to reduce PM emissions by at least 50 percent from the baseline emission level.

(4) Level three: the system has been demonstrated under these procedures to reduce PM emissions by at least 85 percent from the baseline emission level, or to achieve PM emission levels of 0.01 grams per brake-horsepower-hour (g/bhp-hr) or less.

Diesel emission control strategies are categorized by their NOx reductions as follows:

(1) Mark 1: the system has been demonstrated under these procedures to reduce NOx emissions by at least 25 percent from the baseline emission level.

(2) Mark 2: the system has been demonstrated under these procedures to reduce NOx emissions by at least 40 percent from the baseline emission level.

(3) Mark 3: the system has been demonstrated under these procedures to reduce NOx emissions by at least 55 percent from the baseline emission level.

(4) Mark 4: the system has been demonstrated under these procedures to reduce NOx emissions by at least 70 percent from the baseline emission level.

(5) Mark 5: the system has been demonstrated under these procedures to reduce NOx emissions by at least 85 percent from the baseline emission level.

NOTE: Authority cited: Sections 39002, 39003, 39500, 39600, 39601, 39650-39675, 40000, 43000, 43000.5, 43011, 43013, 43018, 43105, 43600 and 43700, Health and Safety Code. Reference: Sections 39650-39675, 43000, 43009.5, 43013, 43018, 43101, 43104, 43105, 43106, 43107 and 43204-43205.5, Health and Safety Code; and Title 17 California Code of Regulations Section 93000.

§ 2709. In-Use Compliance Requirements.

(a) Applicability. These in-use compliance requirements apply to all diesel emission control strategies for on-road, off-road, and stationary applications. It is the responsibility of the applicant to perform in-use compliance testing for each verified diesel emission control strategy family (see Section 2706 (j) (2)). Testing is required when 50 units within a given diesel emission control strategy family have been sold or leased in the California market. Applicants must submit an in-use compliance testing proposal for approval by the Executive Officer prior to the in-use compliance testing. Applicants who have sold 50 units or more but have less than 50 units installed may submit a request for the Executive Officer to delay the in-use compliance deadlines specified in this section.

(b) Test Phases. In-use compliance testing, as described below in subsections (d), (e), (f), and (g), must be conducted per an approved in-use compliance testing proposal at two different phases for each diesel emission control strategy family:
(1) Phase 1. Applicants must obtain and test diesel emission control systems once they have been operated for at least 25 percent of their minimum warranty period or for one year, whichever comes first.
(2) Phase 2. Applicants must obtain and test diesel emission control systems once they have been operated between 60 and 80 percent of their minimum warranty period. For all systems used with heavy heavy-duty vehicles, the 60 to 80 percent window must be applied to the 5 year or 150,000 mile minimum warranty period.

(c) In-Use Compliance Testing Proposal. The applicant must submit to the Executive Officer a Phase 1 in-use compliance testing proposal no later than 90 days after selling the 50^{th} unit. The applicant must submit a Phase 2 in-use compliance testing proposal to the Executive Officer no later than 3 years after the 50^{th} unit is sold. The following information must be included in both testing proposals:
(1) Applicant identification.
(2) Diesel emission control strategy family name.
(3) Parties to be involved in conducting in-use compliance tests.
(4) Test facility identification and description.
(5) Quality control and quality assurance procedures for the test equipment.
(6) List of candidate test units (at least 10 choices per phase) with the following information for each: vehicle/equipment information on which the unit is installed (make, model, model year), location, engine information (family name, make, series, model year, displacement), date of manufacture, date of installation, and cleaning/repair history.
(7) Cumulative sales of the emission control strategy family in each application.

(8) Predicted mileage or hours of use each diesel emission control system will have accrued by the time it is obtained by the applicant of diesel emission control strategy testing.
(9) Description of test vehicles and engines (engine family name, make, model, model year, displacement)
(10) Testing plan for meeting the requirements of part (g) below.

Within 45 days of receipt of the completed testing proposal, the Executive Officer shall determine whether the applicant has an appropriate testing proposal to support in-use compliance testing. The in-use testing proposal will not be considered approved until the Executive Officer issues the applicant a letter of approval. If the Executive Officer determines that the testing proposal is insufficient or inappropriate, the applicant must, within 30 days, submit a revised testing proposal.

(d) Selection of Diesel Emission Control Systems for Testing. For each diesel emission control strategy family and for both test phases, the applicant must propose a representative sample of installed diesel emission control systems for in-use compliance testing based on information provided per Section 2709(c) to be approved by the Executive Officer. The selected diesel emission control systems should come from a representative sample of engines or vehicles equipped with the control systems. The engines or vehicles equipped with the selected diesel emission control systems must have good maintenance records and may receive a tune-up or normal maintenance prior to the applicant obtaining the diesel emission control systems for testing. The applicant must obtain information from the end users regarding the diesel emission control systems' accumulated mileage or hours of usage, maintenance records (to the extent practicable), operating conditions and a description of any unscheduled maintenance that may affect the emission results.

(e) Selection of Test Engines. The Executive Officer must approve the appropriate test engines or vehicles for in-use compliance testing. The applicant must provide candidate test vehicles/engines for the Executive Officer's review. If the Executive Officer determines that a diesel emission control system affects the performance of the engine, the Executive Officer may require the applicant to test the selected diesel emission control system with the engine on which it is installed. The applicant may tune-up or rebuild test engines prior to, but not after, baseline testing unless rebuilding the engine is an integral part of the diesel emission control strategy. All testing should be performed with the test engine in a proper state of maintenance. Emissions of NO_2 from the test engine must not exceed 15 percent of the total baseline NOx emissions by mass. If there is a special category of engines with NO_2 emission levels that normally exceed 15 percent, this requirement may be adjusted for those engines at the discretion of the Executive Officer.

(f) Number of Diesel Emission Control Systems to be Tested. The number of diesel emission control systems an applicant must test in each of the two test phases will be determined as follows:

(1) A minimum of four diesel emission control systems in each diesel emission control strategy family must be tested. For every system tested that does not reduce emissions by at least 90 percent of the lower bound of its initial verification level (or does not achieve an emission level less than or equal to 0.011 g/bhp-hr of PM) or does not meet the NO_2 requirement in section 2709(k), two more diesel emission control systems from the same family must be obtained and tested. The total number of systems tested shall not exceed ten per diesel emission control strategy family.

(2) At the discretion of the Executive Officer, applicants may begin by testing more than the minimum of four diesel emission control systems. Applicants may concede failure of an emission control system before testing a total of ten diesel emission control systems.

(g) In-use Compliance Emission Testing. Applicants must follow the testing procedure used for emission reduction verification as described in Section 2703 (both baseline and control tests are required). As provided in Section 2709(h), the applicant may request the Executive Officer to review and approve an alternative testing procedure. If a diesel emission control strategy verified by U.S. EPA must perform engine dynamometer testing with the Heavy-duty Transient FTP cycle to fulfill the in-use compliance requirements of that program, but was verified by the Executive Officer with chassis dynamometer testing, the Executive Officer will also accept testing with the Heavy-duty Transient FTP cycle for the in-use compliance requirements of this Procedure.

(h) Alternative Test Cycles and Methods. The Executive Officer may consider, on a case by case basis, an alternative test plan or method for applicants to satisfy the in-use compliance requirements of this section. The proposed alternative test plan must be as scientifically sound as the testing described in Section 2709(g) of the Procedure and it must produce accurate results that will indicate if the emission control system reduces emissions to the level for which it was verified. Use of an alternative test procedure must be approved by the Executive Officer.

(i) In-Use Compliance Report. The applicant must submit an in-use compliance report to the Executive Officer after each phase of testing. The applicant must submit the phase 1 report within 18 months from when the 50^{th} unit is sold. The phase 2 report must be submitted within 4 years from when the 50^{th} unit is sold. The following information must be reported for each of the minimum of four diesel emission control systems tested:

(1) Parties involved in conducting the in-use compliance tests.

(2) Quality control and quality assurance information for the test equipment.

(3) Diesel emission control strategy family name and manufacture date.
(4) Vehicle or equipment and type of engine (engine family name, make, model year, model, displacement, etc.) the diesel emission control system was applied to.
(5) Mileage or hours the diesel emission control system was in use.
(6) Results of all emission testing.
(7) Summary of all maintenance, adjustments, modifications, and repairs performed on the diesel emission control system.

(j) The Executive Officer may request the applicant to perform additional in-use testing if the warranty claims exceed four percent of the number of diesel engines using the diesel emission control strategy, or based on other relevant information. As noted in Section 2707(c), if warranty claims exceed four percent of the number of diesel engines using the diesel emission control strategy, the applicant must notify the Executive Officer and submit a warranty report within 30 calendar days of that time.

(k) Conditions for Passing In-Use Compliance Testing. For a diesel emission control strategy to pass in-use compliance testing, emission test results must indicate that the strategy reduced emissions by at least 90 percent of the lower bound of the emission reduction level the Executive Officer originally verified it to. In addition, the strategy must meet the requirements of section 2706(a) with the exception that the strategy must not increase emissions of NO_2 by more than an increment equivalent in mass to 33 or 22 percent of the baseline NOx emission level for systems verified under the 30 or 20 percent NO_2 limits, respectively. If the first four diesel emission control systems tested within a diesel emission control strategy family meet both of these standards, the diesel emission control strategy passes in-use compliance testing. If any of the first four diesel emission control systems tested within a diesel emission control strategy family fail to meet either of these standards, and more than four units are tested, at least 70 percent of all units tested must meet both standards for the diesel emission control strategy family to pass in-use compliance testing. For each failed test, for which the cause of failure can be attributed to the product and not to maintenance or other engine-related problems, two additional units must be tested, up to a total of ten units per diesel emission control strategy family. Within 30 days of a test unit failing, the applicant must submit to the Executive Officer for approval a testing proposal for the additional test units that is compliant with part (c) above. The testing proposal must include an investigative report detailing the causes of the failure. The Executive Officer shall, within 45 days of its receipt, determine whether the test plan is acceptable. After receiving approval from the Executive Officer, the applicant must complete testing.

(l) Failure of In-use Compliance Testing. If a diesel emission control strategy family does not meet the minimum in-use compliance requirements of this

section, the applicant must submit a remedial report within 90 days after the in-use compliance report is submitted. The remedial report must include:
(1) Summary of the in-use compliance report.
(2) Detailed analysis of the failed diesel emission control systems and possible reasons for failure.
(3) Remedial measures to correct or replace failed diesel emission control systems as well as the rest of the in-use diesel emission control systems.

(m) The Executive Officer shall evaluate the remedial report, annual warranty report, and all other relevant information to determine if the diesel emission control strategy family satisfies the in-use compliance requirements. The Executive Officer may request additional information from the applicant. Based on this review, the Executive Officer may lower the verification level or revoke the verification status of a verified diesel emission control strategy family. The Executive Officer may also lower the verification level or revoke the verification status of a verified diesel emission control strategy family, if the applicant does not conduct in-use compliance testing in accordance with this section, or if the Executive Officer conducts in-use compliance testing in accordance with this section (including alternative testing) and the diesel emission control strategy family does not pass the standards in this section.

(n) The Executive Officer may lower the verification level or revoke the verification status of a verified diesel emission control strategy family if the applicant fails to observe the requirements of Sections 2706 or 2707. The Executive Officer must allow the applicant an opportunity to address the possible lowering or revocation of the verification level in a remedial report to the Executive Officer and the Executive Officer may make this determination based on all relevant information.

NOTE: Authority cited: Sections 39002, 39003, 39500, 39600, 39601, 39650-39675, 40000, 43000, 43000.5, 43011, 43013, 43018, 43105, 43600 and 43700, Health and Safety Code. Reference: Sections 39650-39675, 43000, 43009.5, 43013, 43018, 43101, 43104, 43105, 43106, 43107 and 43204-43205.5, Health and Safety Code; and Title 17 California Code of Regulations Section 93000.

§ 2710. Verification of Emission Reductions for Alternative Diesel Fuels and Fuel Additives

(a) Applicability. This section applies to in-use strategies that include emission reductions from the use of alternative diesel fuels or fuel additives. The requirements in this section are in addition to those in Sections 2700-2709, except as specifically noted.

(b) Alternative Diesel Fuel and Fuel Additive Proposed Test Protocol. The applicant must submit a proposed test protocol which includes:

(1) References to criteria pollutant and toxic emissions sampling and analyses that are consistent with the requirements of Section 2703.
(2) Description and Parameters of Alternative Diesel Fuels and Fuel Additives.
  (A) The applicant must describe the applicability of the alternative diesel fuel or fuel additive to diesel engines and identify any requirements for engine or fuel system modifications.
  (B) The applicant must provide a general description of the alternative diesel fuel or fuel additive that includes the fuel type, fuel characteristics, fuel properties, fuel formulation, and chemical composition. The applicant for the candidate alternative diesel fuel or fuel additive must specify the following:
    1. Identity, chemical composition, and concentration of fuel additives
    2. Sulfur content
    3. Total aromatic content
    4. Total polycyclic aromatic hydrocarbon content
    5. Nitrogen content
    6. API gravity (density)
    7. Distillation temperature distribution information, initial boiling point (IBP),
    8. 10% recovered (REC), 5O% REC, 90% REC, and end point (EP)
  (C) The applicant must provide information on the candidate alternative diesel fuel or fuel additive that may affect engine performance, engine wear, and safety. The applicant for the candidate alternative diesel fuel or fuel additive must specify the following:
    1. Viscosity (engine performance)
    2. Fuel volatility (engine performance)
    3. Ignition quality (engine performance)
    4. Fuel operating temperatures (engine performance)
    5. Engine wear tendencies (engine wear)
    6. Corrosion (engine wear)
    7. Lubricity (engine wear)
    8. Fuel flash point (safety)
  (D)The applicant must provide information on the candidate alternative diesel fuel or fuel additive to determine if there are chemicals in the fuel or fuel additive that may increase levels of toxic compounds or potentially form toxic compounds in the fuel or fuel additive. The applicant will conduct an analysis for metals and elements by a method specified by the applicant. Copper, iron, cerium, lead, cadmium, chromium, and phosphorus must be included in the analysis. Additional analysis for other toxic compounds may be required after reviewing the chemical composition of the candidate alternative diesel fuel and its additives or fuel additive (Note: For alternative diesel fuels or fuel additives that are in part comprised of standard diesel fuel, such as emulsified diesel fuels, a toxic analysis of the diesel base fuel is not necessary).

(E) With the approval of the Executive Officer or designee, an applicant may also specify different fuel parameters and test methods that are appropriate to better characterize the candidate alternative diesel fuel or fuel additive.

(3) Upon review of the proposed test protocol, the Executive Officer or designee may require additional fuel components, parameters, and specifications to be determined.

(4) Reference Fuel Specifications. The reference fuel used in the comparative testing described in Section 2710(d) allows the applicant three options in selecting a reference fuel.

(A) Option (1). The first option is to use a 10 percent aromatic California diesel reference fuel. The reference fuel must be produced from straight-run California diesel fuel by a hydrodearomatization process and must have the characteristics set forth below under "Reference Fuel Specifications" (the listed ASTM methods are incorporated herein by reference).

(B) Option (2). The second option is to make the reference fuel from a custom blend using a "like" California diesel fuel made from a straight-run California diesel fuel by a hydroaromatization process and must have the characteristics set forth below under "Reference Fuel Specifications". In addition the reference fuel must exhibit the bell shaped distillation curve characteristic of diesel fuel and no chemical feedstocks or pure chemicals such as solvents can be used as blend stocks. Details of the source and specifications of the feedstocks must be provided in the protocol and the processes and diesel feedstocks used to make the reference fuel must be reviewed and approved by the Executive Officer.

(C) Option (3). For alternative diesel fuels and fuel additives that contain diesel as a base fuel such as emulsified diesel fuel and 80:20 biodiesel fuel (80 percent diesel/20 percent biodiesel), the base diesel fuel used to make the alternative diesel fuel or fuel additive can be used in place of the 10 percent aromatic California diesel reference fuel. The base diesel fuel must be a certified, commercially available diesel fuel sold in California. The sulfur content, aromatic hydrocarbon content, polycyclic aromatic hydrocarbon content, nitrogen content, natural cetane number, API gravity, viscosity, and distillation specifications must be provided for the base diesel fuel used for the reference fuel.

Table 6. Fuel Test Methods and Reference Fuel Specifications

Property	General Reference Fuel Specifications	ASTM Test Method
Sulfur Content	15 ppm max	D5453-93
Aromatic Hydrocarbon content, Vol. %	10% max	D5186-96
Polycyclic Aromatic Hydrocarbon content %	1.4% max	D5186-96
Nitrogen Content	10 ppm max	D4629-96
Natural Cetane Number	48 min	D613-84
Gravity, API	33-39	D287-82
Viscosity at 40^{o}, cSt	2.0-4.1	D445-83
Flash point, ^{o}F	130	D93-80
Distillation, ^{o}F IBP 10%REC 50%REC 90%REC EP	 340-420 400-490 470-560 550-610 580-660	D86-96

(5) The identity of the entity proposed to conduct the tests described in Section 2710(d);
(6) Reasonably adequate quality assurance and quality control procedures;
(7) Notification of any outlier identification and exclusion procedure that will be used, and
(8) A demonstration that any procedure meets generally accepted statistical principles.

(c) Application for Alternative Diesel Fuel and Fuel Additive Emission Reduction Verification. Upon completion of the tests, the applicant may submit an application for verification to the Executive Officer or designee. The application must follow the format in Section 2702(d) as applicable and include:
(1) The approved test protocol,
(2) All of the test data,
(3) Copy of the complete test log prepared in accordance with Section 2710(d)(3)(B),
(4) A demonstration that the candidate alternative diesel fuel or fuel additive meets the requirements for verification set forth in this section, and
(5) Such other information as the Executive Officer or designee may reasonably require.

(d) Emissions Test Procedures for Particulates, Nitrogen Oxides, Soluble Organic Fraction, Hydrocarbons, and Toxics.
(1) Criteria pollutants test requirements. In each test of a fuel, exhaust emissions of NO_x, NO_2 (pursuant to Section 2706(a)(2)), total PM, carbon

monoxide, carbon dioxide, and hydrocarbons must be measured. In addition, for each test the soluble organic fraction (SOF) of the particulate matter in the exhaust emissions must be determined in accordance with the Air Resources Board's "Test Method for Soluble Organic Fraction (SOF) Extraction" dated April 1989, which is incorporated herein by reference.

(2) Toxic emissions sampling and analysis requirements. Exhaust emissions of formaldehyde, acetaldehyde, benzene, toluene, ethyl benzene, xylenes, butadiene, and polycyclic aromatic hydrocarbons are to be sampled and analyzed as specified in Table 7 for a minimum of three test samples collected from separate emission test repetitions.

Table 7. Toxics sampling and analysis [1,2]

Toxics	Method
Formaldehyde and acetaldehyde	ARB SOP 104
Benzene toluene, ethyl benzene, xylenes, and butadiene	ARB SOP 102/103
Polycyclic aromatic hydrocarbons	ARB method 429[3]

[1]Additional toxics sampling may be required depending on the chemical composition of the additives in the fuel.
[2]At a minimum tunnel blanks are required prior to and after conducting toxic emissions sampling for the reference fuel and candidate alternative diesel fuel or fuel additive.
[3]PAH sampling consists of a filter to collect particulate PAHs and XAD resin to collect volatile PAHs. The sampling protocol needs to be included in the test protocol. Analysis of the samples will be performed by ARB method 429.

(3) Emission test requirements and test sequence for emissions test program.

(A) The applicant must follow the emission test requirements from Section 2703 subsections (a), (b), (k), (l), and (m). For all on-road diesel vehicles and equipment, the applicant must conduct engine dynamometer testing using the Federal Test Procedure (FTP) Heavy-duty Transient Cycle, in accordance with the provisions in the Code of Federal Regulations, Title 40, Part 86, Subpart N. For all off-road and stationary diesel vehicles and equipment, the applicant must conduct engine dynamometer testing in accordance with Section 2703(e)(2) and 2703(e)(3). The applicant must use one of the following test sequences:

1. If both cold start and hot start exhaust emission tests are conducted, a minimum of five exhaust emission tests must be performed on the engine with each fuel, using either of the following sequences, where "R" is the reference fuel and "C" is the candidate

alternative diesel fuel or fuel additive: RC CR RC CR RC (and continuing in the same order) or RC RC RC RC RC (and continuing in the same order). The engine mapping procedures and a conditioning transient cycle must be conducted with the reference fuel before each cold start procedure using the reference fuel. The reference cycle used for the candidate alternative diesel fuel or fuel additive must be the same as determined for the reference fuel.

2. If only hot start exhaust emission tests are conducted, one of the following test sequences must be used throughout the testing, where "R" is the reference fuel and "C" is the candidate alternative diesel fuel or fuel additive :

   Alternative 1: RC CR RC CR (continuing in the same order for a given calendar day; a minimum of twenty individual exhaust emission tests must be completed with each fuel)

   Alternative 2: RR CC RR CC (continuing in the same order for a given calendar day; a minimum of twenty individual exhaust emission tests must be completed with each fuel)

   Alternative 3: RRR CCC RRR CCC (continuing in the same order for a given calendar day: a minimum of twenty-one individual exhaust emission tests must be completed with each fuel)

   For all alternatives, an equal number of tests must be conducted using the reference fuel and the candidate alternative diesel fuel or fuel additive on any given calendar day. At the beginning of each calendar day, the sequence of testing must begin with the fuel that was tested at the end of the preceding day. The engine mapping procedures and a conditioning transient cycle must be conducted at the beginning of each day for the reference fuel. The reference cycle used for the candidate alternative diesel fuel or fuel additive must be the same as determined for the reference fuel.

3. Alternative test sequence. The applicant may request the Executive Officer to approve an alternative test sequence in place of the above test sequences. In reviewing this request, the Executive Officer may consider all relevant information including, but not limited to, the following:
   a. Statistical and scientific equivalence to 1. or 2., and
   b. Body of existing test data using the alternative test sequence.

(B) The applicant must submit a test schedule to the Executive Officer or designee at least one week prior to commencement of the tests. The test schedule must identify the days on which the tests will be conducted, and must provide for conducting test consecutively without substantial interruptions other than those resulting from the normal

hours of operations at the test facility. The Executive Officer or designee should be permitted to observe any tests. The party conducting the tests must maintain a test log which identifies all tests conducted, all engine mapping procedures, all physical modifications to or operational tests of the engine, all recalibrations or other changes to the test instruments, and all interruptions between tests, and the reason for each interruption. The party conducting the tests or the applicant must notify the Executive Officer or designee by telephone and in writing of any unscheduled interruption resulting in a test delay of 48 hours or more, and the reason for such delay. Prior to restarting the test, the applicant or person conducting the tests must provide the Executive Officer or designee with a revised schedule for the remaining tests. All tests conducted in accordance with the test schedule, other than any test rejected in accordance with an outlier identification and exclusion procedure included in the approved test protocol, must be included in the comparison of emissions.

(C) Upon approval of the Executive Officer or designee, the applicant may specify an alternative test sequence to Section 2710(d)(3)(A). The applicant must provide the rationale demonstrating that the alternative test sequence better characterizes the average emissions difference between the reference fuel and the alternative diesel fuel or fuel additive.

(e) Durability.

(1) The applicant must meet the durability demonstration requirements in Section 2704 subsections (a), (b), (d), (e), and (h) with the exceptions of emission testing and fuel requirements. If the applicant's diesel emission control strategy includes hardware components in addition to the alternative diesel fuel or fuel additive, then the emission testing requirements in Section 2704 apply.

(2) The applicant must provide test data obtained after completion of the service accumulation, described in Section 2704(d), showing that the candidate alternative diesel fuel or fuel additive does not adversely affect the performance and operation of diesel engines or cause premature wear or cause damage to diesel engines. This must include but is not limited to lubricity, corrosion, and damage to engine parts such as fuel injector tips. The applicant must provide data showing under what temperature and conditions the candidate alternative diesel fuel or fuel additive remains stable and usable in California.

(f) Multimedia Assessment for Fuel Strategies. Diesel emission control strategies which rely on fuel changes either through use of additives or through use of alternative diesel fuels must undergo an evaluation of the multimedia effects. No diesel emission control strategy that relies on the use of an additive or an alternative fuel may be verified unless a multimedia evaluation of the additive or alternative fuel has been conducted and the California Environmental

Policy Council established by Public Resources Code section 71017 has determined that such use will not cause a significant adverse impact on the public health or the environment, pursuant to Health and Safety Code section 43830.8. No person shall sell, offer for sale, supply or offer for supply an alternative fuel or a diesel fuel in California that contains an additive for use in a verified diesel emission control strategy unless such a multimedia evaluation has been conducted and resulted in a determination that use of the alternative fuel or additive will not cause a significant adverse impact on the public health and the environment. The applicant shall bear the expense of conducting the multimedia assessment.

(g) Other Requirements.
(1) The candidate alternative diesel fuel or fuel additive must be in compliance with applicable federal, state, and local government requirements.
(2) Applicants planning to market fuel in California must contact and register with the U.S. EPA and the California Dept. of Food and Agriculture. Contacts are listed below.

Office of Transportation and Air Quality
U.S. EPA Head Quarters
Ariel Rios Blvd.
1200 Pennsylvania Ave, N.W.
Washington DC 20468
Phone (202) 564-9303

Petroleum Products/Weighmaster Enforcement Branch
Division of Measurement Standards
Dept. of Food and Agriculture
8500 Fruitridge Road, Sacramento CA 95826
Phone (916) 229-3000

(3) Additional government agencies such as the California Energy Commission, Area Council of Governments, and Local Air Quality Management Districts may be contacted to facilitate the marketing of alternative diesel fuel in California.

(h) Conditional Verification.
(1) The Executive Officer may grant a conditional verification for an alternative diesel fuel or fuel additive for off-road or stationary applications only after the conditional verification for on-road application is granted. The Executive Officer may grant a conditional verification for on-road application if the applicant meets the following conditions:
(A) The applicant has applied for U.S. EPA registration of the alternative diesel fuel or fuel additive ;

(B) The U.S. EPA has granted a research and development exemption or otherwise granted permission for the alternative diesel fuel or fuel additive to be used, and;
(C) All relevant requirements of Sections 2700-2710 have been met with the exception that registration with the U.S. EPA has not been completed.
(D) Multimedia Assessment as specified in Section 2710 (f).

(2) Where conditional verification is granted, full verification must be obtained by completing the U.S. EPA registration process within a year after receiving conditional verification. During that year, conditional verification is equivalent to verification for the purposes of satisfying the requirements of in-use emission control regulations.

(i) Extensions of an Existing Verification. See Section 2702 (g). The applicant may request the Executive Officer to approve a reduced number of emission tests when extending an existing verification to other emission control groups. In reviewing this request, the Executive Officer may consider all relevant information including, but not limited to, the following:
(1) Variability in the test results used for the existing verification,
(2) Characteristics of the duty cycles in the other emission control groups,
(3) The mechanism by which the alternative diesel fuel or fuel additive reduces emissions, and
(4) Body of existing test data.

Special Note

This December 2010 electronic version of the 1985 Guidelines serves to meet the requirements of Section 508 of the Rehabilitation Act. While converting the 1985 Guidelines to a 508-compliant version, EPA updated the taxonomic nomenclature in the tables of Appendix 1 to reflect changes that occurred since the table were originally produced in 1985. The numbers included for Phylum, Class and Family represent those currently in use from the Integrated Taxonomic Information System, or ITIS, and reflect what is referred to in ITIS as Taxonomic Serial Numbers. ITIS replaced the National Oceanographic Data Center (NODC) taxonomic coding system which was used to create the original taxonomic tables included in the 1985 Guidelines document (NODC, Third Addition - see Introduction). For more information on the NODC taxonomic codes, see http://www.nodc.noaa.gov/General/CDR-detdesc/taxonomic-v8.html.

The code numbers included in the reference column of the tables have not been updated from the 1985 version. These code numbers are associated with the old NODC taxonomic referencing system and are simply replicated here for historical purposes. Footnotes may or may not still apply.

EPA is working on a more comprehensive update to the 1985 Guidelines, including new taxonomic tables which better reflect the large number of aquatic animal species known to be propagating in U.S. waters.

Executive Summary

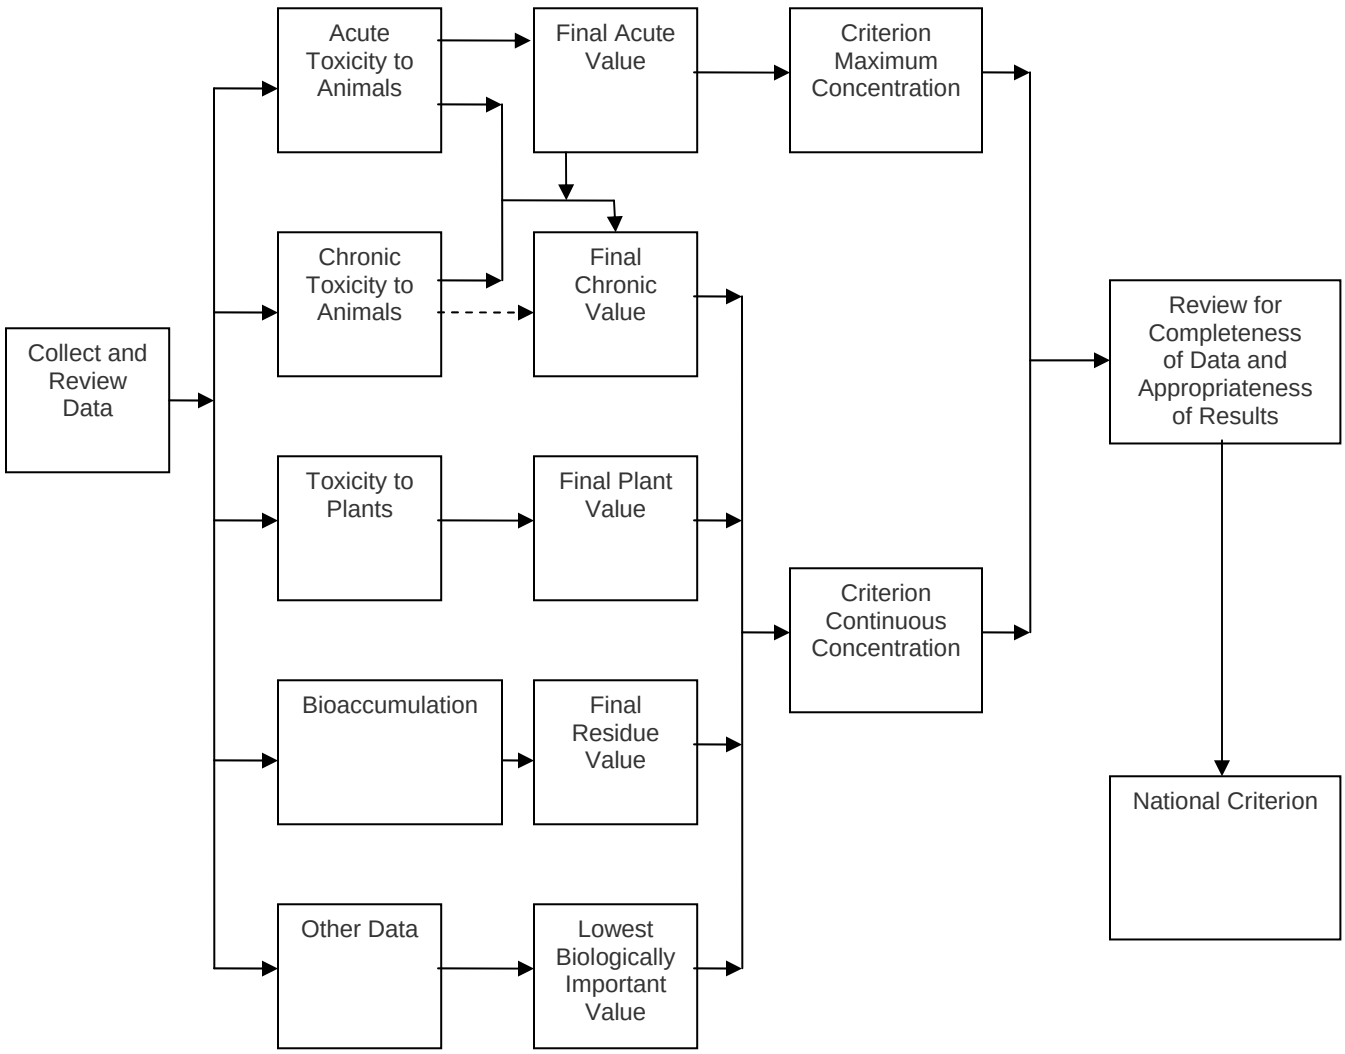
Derivation of numerical national water quality criteria for the protection of aquatic organism and their uses is a complex process (Figure 1) that uses information from many areas of aquatic toxicology. After a decision is made that a national criterion is needed for a particular material, all available information concerning toxicity to, and bioaccumulation by, aquatic organisms is collected, reviewed for acceptability, and sorted. If enough acceptable data on acute toxicity to aquatic animals are available, they are used to estimate the highest one-hour average concentration that should not result in unacceptable effects on aquatic organisms and their uses. If justified, this concentration is made a function of a water quality characteristic such as pH, salinity, or hardness. Similarly, data on the chronic toxicity of the material to aquatic animals are used to estimate the highest four-daily average concentration that should not cause unacceptable toxicity during a long-term exposure. If appropriate, this concentration is also related to a water quality characteristic.

Data on toxicity to aquatic plants are examined to determine whether plants are likely to be unacceptably affected by concentrations that should not cause unacceptable effects on animals. Data on bioaccumulation by aquatic organisms are used to determine if residues might subject edible species to restrictions by the U.S. Food and Drug Administration or if such residues might harm some wildlife consumers of aquatic life. All other available data are examined for adverse effects that might be biologically important.

If a thorough review of the pertinent information indicates that enough acceptable data are available, numerical national water quality criteria are derived for fresh water or salt water or both to protect aquatic organisms and their uses from unacceptable effects due to exposures to high concentrations for short periods of time, lower concentrations for longer periods of time, and combinations of the two.

Figure 1

Derivation of Numerical National Water Quality Crtieria for the Protection of Aquatic Organisms and Their Uses



Introduction

Of the several possible forms of criteria, the numerical form is the most common, but the narrative (e.g., pollutants must not be present in harmful concentrations) and operational (e.g., concentrations of pollutants must not exceed one-tenth of the 96-hr LC50) forms can be used if numerical criteria are not possible or desirable. If it were feasible, a freshwater (or saltwater) numerical aquatic life national criterion* for a material should be determined by conducting field tests on a wide variety of unpolluted bodies of fresh (or salt) water. It would be necessary to add various amounts of the material to each body of water in order to determine the highest concentration that would not cause any unacceptable long-term or short-term effect on the aquatic organisms or their uses. The lowest of these highest concentrations would become the freshwater (or saltwater) national aquatic life water quality criterion for that material, unless one or more of the lowest concentrations were judged to be outliers. Because it is not feasible to determine national criteria by conducting such field tests, these Guidelines for Deriving Numerical National Water Quality Criteria for the Protection of Aquatic Organisms and Their Uses (hereafter referred to as the National Guidelines) describe an objective, internally consistent, appropriate, and feasible way of deriving national criteria, which are intended to provide the same level of protection as the infeasible field testing approach described above.

Because aquatic ecosystems can tolerate some stress and occasional adverse effects, protection of all species at all times and places is not deemed necessary. If acceptable data are available for a large number of appropriate taxa from an appropriate variety of taxonomic and functional groups, a reasonable level of protection will probably be provided if all except a small fraction of the taxa are protected, unless a commercially or recreationally important species is very sensitive. The small fraction is set at 0.05 because other fractions resulted in criteria that seemed too high or too low in comparison with the sets of data from which they were calculated. Use of 0.05 to calculate a Final Acute Value does not imply that this percentage of adversely affected taxa should be used to decide in a field situation whether a criterion is too high or too low or just right.

Determining the validity of a criterion derived for a particular body of water, possibly by modification of a national criterion to reflect local conditions [1, 2, 3], should be based on an operation definition of "protection of aquatic organisms and their uses" that takes into account the practicalities of field monitoring programs and the concerns of the public. Monitoring programs should contain sampling points at enough times and places that all unacceptable changes, whether caused directly or indirectly, will be detected. The programs should adequately monitor the kinds of species of concern to the public, i.e., fish in fresh water and fish and macroinvertebrates in salt water. If the kinds of species of concern cannot be adequately monitored at a reasonable cost, appropriate surrogate species should be monitored. The kinds of species most likely to be good surrogates are those that either (a) are a major food of the desired kinds of species or (b) utilize the same food as the desired species or (c) both. Even if a major adverse effect on appropriate surrogate species does not directly result in an unacceptable effect on the kinds of species of concern to the public, it indicates a high probability that such an effect will occur.

* The term "national criteria" is used herein because it is more descriptive than the synonymous term "section 304(a) criteria", which is used in the Water Quality Standards Regulation [1].

To be acceptable to the public and useful in field situations, protection of aquatic organisms and their uses should be defined as prevention of unacceptable long-term short-term effects on (1) commercially, recreationally, and other important species and (2) (a) fish and benthic invertebrate assemblages in rivers and streams, and (b) fish, benthic invertebrate, and zooplankton assemblages in lakes, reservoirs, estuaries, and oceans. Monitoring programs intended to be able to detect unacceptable effects should be tailored to the body of water of concern so that necessary samples are obtained at enough times and places to provide adequate data on the populations of the important species, as well as data directly related to the reasons for their being considered important. For example, for substances that are residue limited, species that are consumed should be monitored for contaminants to ensure that wildlife predators are protected, FDA action levels are not exceeded, and flavor is not impaired. Monitoring programs should also provide data on the number of taxa and number of individuals in the above-named assemblages that can be sampled at reasonable cost. The amount of decrease in the number of taxa or number of individuals in an assemblage that should be considered unacceptable should take into account appropriate features of the body of water and its aquatic community. Because most monitoring programs can only detect decreases of more than 20 percent, any statistically significant decrease should usually be considered unacceptable. The insensitivity of most monitoring programs greatly limits their usefulness for studying the validity of criteria because unacceptable changes can occur and not be detected. Therefore, although limited field studies can sometimes demonstrate that criteria are underprotective, only high quality field studies can reliably demonstrate that criteria are not underprotective.

If the purpose of water quality criteria were to protect only commercially and recreationally important species, criteria specifically derived to protect such species and their uses from the direct adverse effects of a material would probably, in most situations, also protect those species from indirect adverse effects due to effects of the material on other species in the ecosystem. For example, in most situations either the food chain would be more resistant than the important species and their uses or the important species and their food chains would be adaptable enough to overcome effects of the material on portions of the food chains.

These National Guidelines have been developed on the theory that effects which occur on a species in appropriate laboratory tests will generally occur on the same species in comparable field situations. All North American bodies of water and resident aquatic species and their uses are meant to be taken into account, except for a few that may be too atypical, such as the Great Salt Lake, brine shrimp, and the siscowet subspecies of lake trout, which occurs in Lake Superior and contains up to 67% fat in the fillets [4]. Derivation of criteria specifically for the Great Salt Lake or Lake Superior might have to take brine shrimp and siscowet, respectively, into account.

Numerical aquatic life criteria derived using these National Guidelines are expressed as two numbers, rather than the traditional one number, so that the criteria more accurately reflect toxicological and practical realities. If properly derived and used, the combination of a maximum concentration and a continuous concentration should provide an appropriate degree of protection of aquatic organisms and their uses from acute and chronic toxicity to animals, toxicity to plants, and bioaccumulation by aquatic organisms, without being as restrictive as a one-number criterion would have to be in order to provide the same degree of protection.

Criteria produced by these Guidelines are intended to be useful for developing water quality standards, mixing zone standards, effluent limitations, etc. The development of such standards

and limitations, however, might have to take into account such additional factors as social, legal, economic, and hydrological considerations, the environmental and analytical chemistry of the material, the extrapolation from laboratory data to field situations, and relationships between species for which data are available and species in the body of water of concern. As an intermediate step in the development of standards, it might be desirable to derive site-specific criteria by modification of national criteria to reflect such local conditions as water quality, temperature, or ecologically important species [1, 2, 3]. In addition, with appropriate modifications these National Guidelines can be used to derive criteria for any specific geographical area, body of water (such as the Great Salt Lake), or group of similar bodies of water, if adequate information is available concerning the effects of the material of concern on appropriate species and their uses.

Criteria should attempt to provide a reasonable and adequate amount of protection with only a small possibility of considerable overprotection or underprotection. It is not enough that a national criterion be the best estimate that can be obtained using available data; it is equally important that a criterion be derived only if adequate appropriate data are available to provide reasonable confidence that it is a good estimate. Therefore, these National Guidelines specify certain data that should be available if a numerical criterion is to be derived. If all the required data are not available, usually a criterion should not be derived. On the other hand, the availability of all required data does not ensure that a criterion can be derived.

A common belief is that national criteria are based on "worst case" assumptions and that local considerations will raise, but not lower, criteria. For example, it will usually be assumed that if the concentration of a material in a body of water is lower than the national criterion, no unacceptable effects will occur and no site-specific criterion needs to be derived. If, however, the concentration of a material in a body of water is higher than the national criterion, it will usually be assumed that a site-specific criterion should be derived. In order to prevent the assumption of the "worst case" nature of national criteria from resulting in the underprotection of too many bodies of water, national criteria must be intended to protect all or almost all bodies of water. Thus, if bodies of water and the aquatic communities in them do differ substantially in their sensitivities to a material, national criteria should be at least somewhat overprotective for a majority of the bodies of water. To do otherwise would either (a) require derivation of site-specific criteria even if the site-specific concentration were substantially below the national criterion or (b) cause the "worst case" assumption to result in the underprotection of numerous bodies of water. On the other hand, national criteria are probably underprotective of some bodies of water.

The two factors that will probably cause the most difference between national and site-specific criteria are the species that will be exposed and the characteristics of the water. In order to ensure that national criteria are appropriately protective, the required data for national criteria include some species that are sensitive to many materials and national criteria are specifically based on tests conducted in water relatively low in particulate matter and organic matter. Thus, the two factors that will usually be considered in the derivation of site-specific criteria from national criteria are used to help ensure that national criteria are appropriately protective.

On the other hand, some local conditions might require that site-specific criteria be lower than national criteria. Some untested locally important species might be very sensitive to the material of concern, and local water quality might not reduce the toxicity of the material. In addition,

aquatic organisms in field situations might be stressed by diseases, parasites, predators, other pollutants, contaminated or insufficient food, and fluctuating and extreme conditions of flow, water quality, and temperature. Further, some materials might degrade to more toxic materials, or some important community functions or species interactions might be adversely affected by concentrations lower than those that affect individual species.

Criteria must be used in a manner that is consistent with the way in which they were derived if the intended level of protection is to be provided in the real world. Although derivation of water quality criteria for aquatic life is constrained by the ways toxicity and bioconcentration tests are usually conducted, there are still many different ways that criteria can be derived, expressed, and used. The means used to derive and state criteria should relate, in the best possible way, the kinds of data that are available concerning toxicity and bioconcentration and the ways criteria can be used to protect aquatic organisms and their uses.

The major problem is to determine the best way that the statement of a criterion can bridge the gap between the nearly constant concentrations used in most toxicity and bioconcentration tests and the fluctuating concentrations that usually exist in the real world. A statement of a criterion as a number that is not to be exceeded any time or place is not acceptable because few, if any, people who use criteria would take it literally and few, if any, toxicologists would defend a literal interpretation. Rather than try to reinterpret a criterion that is neither useful nor valid, it is better to develop a more appropriate way of stating criteria.

Although some materials might not exhibit thresholds, many materials probably do. For any threshold material, continuous exposure to any combination of concentrations below the threshold will not cause an unacceptable effect (as defined on pages 1 and 2) on aquatic organisms and their uses, except that the concentration of a required trace nutrient might be too low. However, it is important to note that this is a threshold of unacceptable effect, not a threshold of adverse effect. Some adverse effect, possibly even a small reduction in the survival, growth, or reproduction of a commercially or recreationally important species, will probably occur at, and possibly even below, the threshold. The Criterion Continuous Concentration (CCC) is intended to be a good estimate of this threshold of unacceptable effect. If maintained continuously, any concentration above the CCC is expected to cause an unacceptable effect. On the other hand, the concentration of a pollutant in a body of water can be above the CCC without causing an unacceptable effect if (a) the magnitudes and durations of the excursions above the CCC are appropriately limited and (b) there are compensating periods of time during which the concentration is below the CCC. The higher the concentration is above the CCC, the shorter the period of time it can be tolerated. But it is unimportant whether there is any upper limit on concentrations that can be tolerated instantaneously or even for one minute because concentrations outside mixing zones rarely change substantially in such short periods of time.

An elegant, general approach to the problem of defining conditions (a) and (b) would be to integrate the concentration over time, taking into account uptake and depuration rates, transport within the organism to a critical site, etc. Because such an approach is not currently feasible, an approximate approach is to require that the average concentration not exceed the CCC. The average concentration should probably be calculated as the arithmetic average rather than the geometric mean [5]. If a suitable averaging period is selected, the magnitudes and durations of concentrations above the CCC will be appropriately limited, and suitable compensating periods below the CCC will be required.

In the elegant approach mentioned above, the uptake and depuration rates would determine the effective averaging period, but these rates are likely to vary from species to species for any particular material. Thus the elegant approach might not provide a definitive answer to the problem of selecting an appropriate averaging period. An alternative is to consider that the purpose of the averaging period is to allow the concentration to be above the CCC only if the allowed fluctuating concentrations do not cause more adverse effect than would be caused by a continuous exposure to the CCC. For example, if the CCC caused a 10% reduction in growth of rainbow trout, or a 13% reduction in survival of oysters, or a 7% reduction in reproduction of smallmouth bass, it is the purpose of the averaging period to allow concentrations above the CCC only if the total exposure will not cause any more adverse effect than continuous exposure to the CCC would cause.

Even though only a few tests have compared the effects of a constant concentration with the effects of the same average concentration resulting from a fluctuating concentration, nearly all the available comparisons have shown that substantial fluctuations result in increased adverse effects [5, 6]. Thus if the averaging period is not to allow increased adverse effects, it must not allow substantial fluctuations. Life-cycle tests with species such as mysids and daphnids and early life-stage tests with warmwater fishes usually last for 20 to 30 days. An averaging period that is equal to the length of the test will obviously allow the worst possible fluctuations and would very likely allow increased adverse effects.

An averaging period of four days seems appropriate for use with the CCC for two reasons. First, it is substantially shorter than the 20 to 30 days that is obviously unacceptable. Second, for some species it appears that the results of chronic tests are due to the existence of a sensitive life stage at some time during the test [7], rather than being caused by either long-term stress or long-term accumulation of the test material in the organism. The existence of a sensitive life stage is probably the cause of acute-chronic ratios that are not much greater than 1, and is also possible when the ratio is substantially greater than 1. In addition, some experimentally determined acute-chronic ratios are somewhat less than 1, possibly because prior exposure during the chronic test increased the resistance of the sensitive life stage [8]. A four-day averaging period will probably prevent increased adverse effects on sensitive life stages by limiting the durations and magnitudes of exceedences[*] of the CCC.

The considerations applied to interpretation of the CCC also apply to the CMC. For the CMC the averaging period should again be substantially less than the lengths of the tests it is based on, i.e., substantially less than

48 to 96 hours. One hour is probably an appropriate averaging period because high concentrations of some materials can cause death in one to three hours. Even when organisms do not die within the first hour or so, it is not known how many might have died due to delayed effects of this short of an exposure. Thus it is not appropriate to allow concentrations above the CMC to exist for as long as one hour.

The durations of the averaging periods in national criteria have been made short enough to restrict allowable fluctuations in the concentration of the pollutant in the receiving water and to restrict the length of time that the concentration in the receiving water can be continuously above

[*] Although "exceedence" has not been found in any dictionary, it is used here because it is not appropriate to use "violation" in conjunction with criteria, no other word seems appropriate, and all appropriate phrases are awkward.

a criterion concentrations. The statement of a criterion could specify that the four-day average should never exceed the CCC and that the one-hour average should never exceed the CMC. However, one of the most important uses of criteria is for designing waste treatment facilities. Such facilities are designed based on probabilities and it is not possible to design for a zero probability. Thus, one of the important design parameters is the probability that the four-day average or the one-hour-average will be exceeded, or, in other words, the frequency with which exceedences will be allowed.

The frequency of allowed exceedences should be based on the ability of aquatic ecosystems to recover from the exceedences, which will depend in part on the magnitudes and durations of the exceedences. It is important to realize that high concentrations caused by spills and similar major events are not what is meant by an "exceedence", because spills and other accidents are not part of the design of the normal operation of waste treatment facilities. Rather, exceedences are extreme values in the distribution of ambient concentrations and this distribution is the result of the usual variations in the flows of both the effluent and the receiving water and the usual variations in the concentrations of the material of concern in both the effluent and in the upstream receiving water. Because exceedences are the result of usual variation, most of the exceedences will be small and exceedences as large as a factor of two will be rare. In addition, because these exceedences are due to random variation, they will not be evenly spaced. In fact, because many receiving waters have both one-year and multi-year cycles and many treatment facilities have daily, weekly, and yearly cycles, exceedences will often be grouped, rather than being evenly spaced or randomly distributed. If the flow of the receiving water is usually much greater than the flow of the effluent, normal variation and the flow cycles will result in the ambient concentration usually being below the CCC, occasionally being near the CCC, and rarely being above the CCC. In addition, exceedences that do occur will be grouped. On the other hand, if the flow of the effluent is much greater than the flow of the receiving water, the concentration might be close to the CCC much of the time and rarely above the CCC, with exceedences being randomly distributed.

The abilities of ecosystems to recover differ greatly, and depend on the pollutant, the magnitude and duration of the exceedence, and the physical and biological features of the ecosystem. Documented studies of recoveries are few, but some systems recover from small stresses in six weeks whereas other systems take more than ten years to recover from severe stress [3]. Although most exceedences are expected to be very small, larger exceedences will occur occasionally. Most aquatic ecosystems can probably recover from most exceedences in about three years. Therefore, it does not seem reasonable to purposely design for stress above that caused by the CCC to occur more than once every three years on the average, just as it does not seem reasonable to require that these kinds of stresses only occur once every five or ten years on the average.

If the body of water is not subject to anthropogenic stress other than the exceedences of concern and if exceedences as large as a factor of two are rare, it seems reasonable that most bodies of water could tolerate exceedences once every three years on the average. In situations in which exceedences are grouped, several exceedences might occur in one or two years, but then there will be, for example, 10 to 20 years during which no exceedences will occur and the concentration will be substantially below the CCC most of the time. In situations in which the concentration is often close to the CCC and exceedences are randomly distributed, some adverse effect will occur regularly, and small additional, unacceptable effects will occur about every

third year. The relative long-term ecological consequences of evenly spaced and grouped exceedences are unknown, but because most exceedences will probably be small, the long-term consequences should be about equal over long periods of time.

The above considerations lead to a statement of a criterion in the frequency-intensity-duration format that is often used to describe rain and snow fall and stream flow, e.g., how often, on the average, does more than ten inches of rain fall in a week? The numerical values chosen for frequency (or average recurrence interval), intensity (i.e., concentration), and duration (of averaging period) are those appropriate for national criteria. Whenever adequately justified, a national criterion may be replaced by a site-specific criterion [1], which may include not only site-specific criterion concentrations [2], but also site-specific durations of averaging periods and site-specific frequencies of allowed exceedences [3].

The concentrations, durations, and frequencies specified in criteria are based on biological, ecological, and toxicological data, and are designed to protect aquatic organisms and their uses from unacceptable effects. Use of criteria for designing waste treatment facilities requires selections of an appropriate wasteload allocation model. Dynamic models are preferred for the application of water quality criteria, but a steady-state model might have to be used instead of a dynamic model in some situations. Regardless of the model that is used, the durations of the averaging periods and the frequencies of allowed exceedences must be applied correctly if the intended level of protection is to be provided. For example, in the criterion statement frequency refers to the average frequency, over a long period of time, of rare events (i.e., exceedences). However, in some disciplines, frequency is often thought of in terms of the average frequency, over a long period of time, of the years is which rare events occur, without any consideration of how many rare events occur within each of those eventful years. The distinction between the frequency of events and the frequency of years in important for all those situations in which the rare events, e.g., exceedences, tend to occur in groups within the eventful years. The two ways of calculating frequency produce the same results in situations in which each rare event occurs in a different year because then the frequency of events is the same as the frequency of eventful years.

Because fresh water and salt water have basically different chemical compositions and because freshwater and saltwater (i.e., estuarine and true marine) species rarely inhabit the same water simultaneously, these National Guidelines provide for the derivation of separate criteria for these two kinds of water. For some materials sufficient data might not be available to allow derivation of criteria for one or both kinds of water. Even though absolute toxicities might be different in fresh and salt waters, such relative data as acute-chronic ratios and bioconcentration factors often appear to be similar in the two waters. When data are available to indicate that these ratios and factors are probably similar, they are used interchangeably.

The material for which a criterion is desired is usually defined in terms of a particular chemical compound or ion, or a group of closely related compounds or ions, but it might possibly be defined in terms of an effluent. These National Guidelines might also be useful for deriving criteria for temperature, dissolved oxygen, suspended solids, pH, etc., if the kinds of data on which the Guidelines are based are available.

Because they are meant to be applied only after a decision has been made that a national water quality criterion for aquatic organisms is needed for a material, these National Guidelines do not

address the rationale for making that decision. If the potential for adverse effects on aquatic organisms and their uses is part of the basis for deciding whether an aquatic life criterion is needed for a material, these Guidelines will probably be helpful in the collection and interpretation of relevant data. Such properties as volatility might affect the fate of a material in the aquatic environment and might be important when determining whether a criterion is needed for a material; for example, aquatic life criteria might not be needed for materials that are highly volatile or highly degradable in water. Although such properties can affect how much of the material will get from the point of discharge through any allowed mixing zone to some portion of the ambient water and can also affect the size of the zone of influence in the ambient water, such properties do not affect how much of the material aquatic organisms can tolerate in the zone of influence.

This version of the National Guidelines provides clarifications, additional details, and technical and editorial changes from the previous version [9]. These modifications are the result of comments on the previous version and subsequent drafts [10], experience gained during the U.S. EPA's use of previous versions and drafts, and advances in aquatic toxicology and related fields. Future versions will incorporate new concepts and data as their usefulness is demonstrated. The major technical changes incorporated into this version of the National Guidelines are:

1. The requirement for acute data for freshwater animals has been changed to include more tests with invertebrate species. The taxonomic, functional, and probably the toxicological, diversities among invertebrate species are greater than those among vertebrate species and this should be reflected in the required data.

2. When available, 96-hr EC50s based on the percentage of fish immobilized plus the percentage of fish killed are used instead of 96-hr LC50s for fish; comparable EC50s are used instead of LC50s for other species. Such appropriately defined EC50s better reflect the total severe acute adverse impact of the test material on the test species than do LC50s or narrowly defined EC50s. Acute EC50s that are based on effects that are not severe, such as reduction in shell deposition and reduction in growth, are not used in calculating the Final Acute Value.

3. The Final Acute Value is now defined in terms of Genus Mean Acute Values rather than Species Mean Acute Values. A Genus Mean Acute Value is the geometric mean of all the Species Mean Acute Values available for species in the genus. On the average, species within a genus are toxicologically much more similar than species in different genera, and so the use of Genus Mean Acute Values will prevent data sets from being biased by an overabundance of species in one or a few genera.

4. The Final Acute Value is now calculated using a method [11] that is not subject to the bias and anomalous behavior that the previous method was. The new method is also less influenced by one very low value because it always gives equal weight to the four values that provide the most information about the cumulative probability of 0.05. Although the four values receive the most weight, the other values do have a substantial effect on the Final Acute Value (see examples in Appendix 2).

5. The requirements for using the results of tests with aquatic plants have been made more stringent.

6. Instead of being equal to the Final Acute Value, the Criterion Maximum Concentration is now equal to one-half the Final Acute Value. The Criterion Maximum Concentration is intended to protect 95 percent of a group of diverse genera, unless a commercially or recreationally important species is very sensitive. However, a concentration that would severely harm 50 percent of the fifth percentile or 50 percent of a sensitive important species cannot be considered to be protective of that percentile or that species. Dividing the Final Acute Value by 2 is intended to result in a concentration that will not severely adversely affect too many of the organisms.

7. The lower of the two numbers in the criterion is now called the Criterion Continuous Concentration, rather than the Criterion Average Concentration, to more accurately reflect the nature of the toxicological data on which it is based.

8. The statement of a criterion has been changed (a) to include durations of averaging periods and frequencies of allowed exceedences that are based on what aquatic organisms and their uses can tolerate, and (b) to identify a specific situation in which site-specific criteria [1, 2, 3] are probably desirable.

In addition, Appendix 1 was added to aid in determining whether a species should be considered resident in North America and its taxonomic classification. Appendix 2 explains the calculation of the Final Acute Value.

The amount of guidance in these National Guidelines has been increased, but much of the guidance is necessarily qualitative rather than quantitative; much judgment will usually be required to derive a water quality criterion for aquatic organisms and their uses. In addition, although this version of the National Guidelines attempts to cover all major questions that have arisen during use of previous versions and drafts, it undoubtedly does not cover all situations that might occur in the future. All necessary decisions should be based on a thorough knowledge of aquatic toxicology and an understanding of these Guidelines and should be consistent with the spirit of these Guidelines, i.e., to make best use of the available data to derive the most appropriate criteria. These National Guidelines should be modified whenever sound scientific evidence indicates that a national criterion produced using these Guidelines would probably be substantially overprotective or underprotective of the aquatic organisms and their uses on a national basis. Derivation of numerical national water quality criteria for aquatic organisms and their uses is a complex process and requires knowledge in many areas of aquatic toxicology; any deviation from these Guidelines should be carefully considered to ensure that it is consistent with other parts of these Guidelines.

I. Definition of Material of Concern

A. Each separate chemical that does not ionize substantially in most natural bodies of water should usually be considered a separate material, except possibly for structurally similar organic compounds that only exist in large quantities as commercial mixtures of various compounds and apparently have similar biological, chemical, physical, and toxicological properties.

B. For chemicals that do ionize substantially in most natural bodies of water (e.g., some phenols and organic acids, some salts of phenols and organic acids, and most

inorganic salts and coordination complexes of metals), all forms that would be in chemical equilibrium should usually be considered one material. Each different oxidation state of a metal and each different nonionizable covalently bonded organometallic compound should usually be considered a separate material.

C. The definition of the material should include an operational analytical component. Identification of a material simply, for example, as "sodium" obviously implies "total sodium", but leaves room for doubt. If "total" is meant, it should be explicitly stated. Even "total" has different operational definitions, some of which do not necessarily measure "all that is there" in all samples. Thus, it is also necessary to reference or describe the analytical method that is intended. The operational analytical component should take into account the analytical and environmental chemistry of the material, the desirability of using the same analytical method on samples from laboratory tests, ambient water, and aqueous effluents, and various practical considerations, such as labor and equipment requirements and whether the method would require measurement in the field or would allow measurement after samples are transported to a laboratory.

The primary requirements of the operational analytical component are that it be appropriate for use on samples of receiving water, that it be compatible with the available toxicity and bioaccumulation data without making extrapolations that are too hypothetical, and that it rarely result in underprotection or overprotection of aquatic organisms and their uses. Because an ideal analytical measurement will rarely be available, a compromise measurement will usually have to be used. This compromise measurement must fit with the general approach that if an ambient concentration is lower than the national criterion, unacceptable effects will probably not occur, i.e., the compromise measurement must not err on the side of underprotection when measurements are made on a surface water. Because the chemical and physical properties of an effluent are usually quite different from those of the receiving water, an analytical method that is acceptable for analyzing an effluent might not be appropriate for analyzing a receiving water, and vice versa. If the ambient concentration *calculated* from a measured concentration in an effluent is higher than the national criterion, an additional option is to *measure* the concentration after dilution of the effluent with receiving water to determine if the measured concentration is lowered by such phenomena as complexation or sorption. A further option, of course, is to derive a site-specific criterion [1, 2, 3]. Thus, the criterion should be based on an appropriate analytical measurement, but the criterion is not rendered useless if an ideal measurement either is not available or is not feasible.

NOTE: The analytical chemistry of the material might have to be taken into account when defining the material or when judging the acceptability of some toxicity tests, but a criterion should not be based on the sensitivity of an analytical method. When aquatic organisms are more sensitive than routine analytical methods, the proper solution is to develop better analytical methods, not to underprotect aquatic life.

II. Collection of Data

A. Collect all available data on the material concerning (a) toxicity to, and bioaccumulation by, aquatic animals and plants, (b) FDA action levels [12], and (c) chronic feeding studies and long-term field studies with wildlife species that regularly consume aquatic organisms.

B. All data that are used should be available in typed, dated, and signed hard copy (publication, manuscript, letter, memorandum, etc.) with enough supporting information to indicate that acceptable test procedures were used and that the results are probably reliable. In some cases it may be appropriate to obtain additional written information from the investigator, if possible. Information that is confidential or privileged or otherwise not available for distribution should not be used.

C. Questionable data, whether published or unpublished, should not be used. For example, data should usually be rejected if they are from tests that did not contain a control treatment, tests in which too many organisms in the control treatment died or showed signs of stress or disease, and tests in which distilled or deionized water was used as the dilution water without addition of appropriate salts.

D. Data on technical grade materials may be used if appropriate, but data on formulated mixtures and emulsifiable concentrates of the material of concern should not be used.

E. For some highly volatile, hydrolyzable, or degradable materials it is probably appropriate to use only results of flow-through tests in which the concentrations of test material in the test solutions were measured often enough using acceptable analytical methods.

F. Data should be rejected if they were obtained using:

1. Brine shrimp, because they usually only occur naturally in water with salinity greater than 35 g/kg.

2. Species that do not have reproducing wild populations in North America (see Appendix 1).

3. Organisms that were previously exposed to substantial concentrations of the test material or other contaminants.

G. Questionable data, data on formulated mixtures and emulsifiable concentrates, and data obtained with non-resident species in North America or previously exposed organisms may be used to provide auxiliary information but should not be used in the derivation of criteria.

III. Required data

A. Certain data should be available to help ensure that each of the four major kinds of possible adverse effects receives adequate consideration. Results of acute and chronic toxicity tests with representative species of aquatic animals are necessary so that data available for tested species can be considered a useful indication of the sensitivities of

appropriate untested species. Fewer data concerning toxicity to aquatic plants are required because procedures for conducting tests with plants and interpreting the results of such tests are not as well developed. Data concerning bioaccumulation by aquatic organisms are only required if relevant data are available concerning the significance of residues in aquatic organisms.

B. To derive a criterion for freshwater aquatic organisms and their uses, the following should be available:

1. Results of acceptable acute tests (see Section IV) with at least one species of freshwater animal in at least eight different families such that all of the following are included:

    a. the family Salmonidae in the class Osteichthyes

    b. a second family in the class Osteichthyes, preferably a commercially or recreationally important warmwater species (e.g., bluegill, channel catfish, etc.)

    c. a third family in the phylum Chordata (may be in the class Osteichthyes or may be an amphibian, etc.)

    d. a planktonic crustacean (e.g., cladoceran, copepod, etc.)

    e. a benthic crustacean (e.g., ostracod, isopod, amphipod, crayfish, etc.)

    f. an insect (e.g., mayfly, dragonfly, damselfly, stonefly, caddisfly, mosquito, midge, etc.)

    g. a family in a phylum other than Arthropoda or Chordata (e.g., Rotifera, Annelida, Mollusca, etc.)

    h. a family in any order of insect or any phylum not already represented.

2. Acute-chronic ratios (see Section VI) with species of aquatic animals in at least three different families provided that one of the three species:

    - at least one is a fish
    - at least one is an invertebrate
    - at least one is an acutely sensitive freshwater species (the other two may be saltwater species).

3. Results of at least one acceptable test with a freshwater alga or vascular plant (see Section VIII). If plants are among the aquatic organisms that are most sensitive to the material, results of a test with a plant in another phylum (division) should also be available.

4. At least one acceptable bioconcentration factor determined with an appropriate freshwater species, if a maximum permissible tissue concentration is available (see Section IX).

C. To derive a criterion for saltwater aquatic organisms and their uses, the following should be available:

1. Results of acceptable acute tests (see Section IV) with at least one species of saltwater animal in at least eight different families such that all of the following are included:

    a. two families in the phylum Chordata

    b. a family in a phylum other than Arthropoda or Chordata

    c. either the Mysidae or Penaeidae family

    d. three other families not in the phylum Chordata (may include Mysidae or Penaeidae, whichever was not used above)

    e. any other family.

2. Acute-chronic ratios (see Section VI) with species of aquatic animals in at least three different families provided that of the three species:

    - at least one is a fish
    - at least one is an invertebrate
    - at least one is an acutely sensitive saltwater species (the other two may be freshwater species).

3. Results of at least one acceptable test with a saltwater alga or vascular plant (see Section VIII). If plants are among the aquatic organisms most sensitive to the material, results of a test with a plant in another phylum (division) should also be available.

4. At least one acceptable bioconcentration factor determined with an appropriate saltwater species, if a maximum permissible tissue concentration is available (see Section IX).

D. If all the required data are available, a numerical criterion can usually be derived, except in special cases. For example, derivation of a criterion might not be possible if the available acute-chronic ratios vary by more than a factor of ten with no apparent pattern. Also, if a criterion is to be related to a water quality characteristic (see Sections V and VII), more data will be necessary.

Similarly, if all required data are not available, a numerical criterion should not be derived except in special cases. For example, even if not enough acute and chronic data are available, it might be possible to derive a criterion if the available data

clearly indicate that the Final Residue Value should be much lower than either the Final Chronic Value or Final Plant Value.

E. Confidence in a criterion usually increases as the amount of available pertinent data increases. Thus, additional data are usually desirable.

IV. Final Acute Value

A. Appropriate measures of the acute (short-term) toxicity of the material to a variety of species of aquatic animals are used to calculate the Final Acute Value. The Final Acute Value is an estimate of the concentration of the material corresponding to a cumulative probability of 0.05 in the acute toxicity values for the genera with which acceptable acute tests have been conducted on the material. However, in some cases, if the Species Mean Acute Value of a commercially or recreationally important species is lower than the calculated Final Acute Value, then that Species Mean Acute Value replaces the calculated Final Acute Value in order to provide protection for that important species.

B. Acute toxicity tests should have been conducted using acceptable procedures [13].

C. Except for test with saltwater annelids and mysids, results of acute tests during which the test organisms were fed should not be used, unless data indicate that the food did not affect the toxicity of the test material.

D. Results of acute tests conducted in unusual dilution water, e.g., dilution water in which total organic carbon or particulate matter exceeded 5 mg/L, should not be used, unless a relationship is developed between acute toxicity and organic carbon or particulate matter or unless data show that organic carbon, particulate matter, etc., do not affect toxicity.

E. Acute values should be based on endpoints which reflect the total severe acute adverse impact of the test material on the organisms used in the test. Therefore, only the following kinds of data on acute toxicity to aquatic animals should be used:

1. Tests with daphnids and other cladocerans should be started with organisms less than 24 hours old and tests with midges should be started with second- or third-instar larvae. The result should be the 48-hr EC50 based on percentage of organisms immobilized plus percentage of organisms killed. If such an EC50 is not available from a test, the 48-hr LC50 should be used in place of the desired 48-hr EC50. An EC50 or LC50 of longer than 48 hr can be used as long as the animals were not fed and the control animals were acceptable at the end of the test.

2. The result of a test with embryos and larvae of barnacles, bivalve molluscs (clams, mussels, oysters, and scallops), sea urchins, lobsters, crabs, shrimp, and abalones, should be the 96-hr EC50 based on the percentage of organisms with incompletely developed shells plus the percentage of organisms killed. If such an EC50 is not available from a test, the lower of the 96-hr EC50 based on the percentage of organisms with incompletely developed shells and the 96-hr LC50

should be used in place of the desired 96-hr EC50. If the duration of the test was between 48 and 96 hr, the EC50 or LC50 at the end of the test should be used.

3. The acute values from tests with all other freshwater and saltwater animal species and older life stages of barnacles, bivalve molluscs, sea urchins, lobsters, crabs, shrimps, and abalones should be the 96-hr EC50 based on the percentage of organisms exhibiting loss of equilibrium plus the percentage of organisms immobilized plus the percentage of organisms killed. If such an EC50 is not available from a test, the 96-hr LC50 should be used in place of the desired 96-hr EC50.

4. Tests with single-celled organisms are not considered acute tests, even if the duration was 96 hours or less.

5. If the tests were conducted properly, acute values reported as "greater than" values and those which are above the solubility of the test material should be used, because rejection of such acute values would unnecessarily lower the Final Acute Value by eliminating acute values for resistant species.

F. If the acute toxicity of the material to aquatic animals apparently has been shown to be related to a water quality characteristic such as hardness or particulate matter for freshwater animals or salinity or particulate matter for saltwater animals, a Final Acute Equation should be derived based on that water quality characteristic. Go to Section V.

G. If the available data indicate that one or more life stages are at least a factor of two more resistant than one or more other life stages of the same species, the data for the more resistant life stages should not be used in the calculation of the Species Mean Acute Value because a species can only be considered protected from acute toxicity if all life stages are protected.

H. The agreement of the data within and between species should be considered. Acute values that appear to be questionable in comparison with other acute and chronic data for the same species and for other species in the same genus probably should not be used in calculation of a Species Mean Acute Value. For example, if the acute values available for a species or genus differ by more than a factor of 10, some or all of the values probably should not be used in calculations.

I. For each species for which at least one acute value is available, the Species Mean Acute Value (SMAV) should be calculated as the geometric mean of the results of all flow-through tests in which the concentrations of test material were measured. For a species for which no such result is available, the SMAV should be calculated as the geometric mean of all available acute values, i.e., results of flow-through tests in which the concentrations were not measured and results of static and renewal tests based on initial concentrations (nominal concentrations are acceptable for most test materials if measured concentrations are not available) of test material.

NOTE: Data reported by original investigators should not be rounded off. Results of all intermediate calculations should be rounded [14] to four significant digits.

NOTE: The geometric mean of N numbers is the Nth root of the product of the N numbers. Alternatively, the geometric mean can be calculated by adding the logarithms of the N numbers, dividing the sum by N, and taking the antilog of the quotient. The geometric mean of two numbers is the square root of the product of the two numbers, and the geometric mean of one number is that number. Either natural (base e) or common (base 10) logarithms can be used to calculate geometric means as long as they are used consistently within each set of data, i.e., the antilog used must match the logarithm used.

NOTE: Geometric means, rather than arithmetic means, are used here because the distributions of sensitivities of individual organisms in toxicity tests on most materials and the distributions of sensitivities of species within a genus are more likely to be lognormal than normal. Similarly, geometric means are used for acute-chronic ratios and bioconcentration factors because quotients are likely to be closer to lognormal than normal distributions. In addition, division of the geometric mean of a set of numerators by the geometric mean of the set of corresponding denominators will result in the geometric mean of the set of corresponding quotients.

J. For each genus for which one or more SMAVs are available, the Genus Mean Acute Value (GMAV) should be calculated as the geometric mean of the SMAVs available for the genus.

K. Order the GMAVs from high to low.

L. Assign ranks, R, to the GMAVs from "1" for the lowest to "N" for the highest. If two or more GMAVs are identical, arbitrarily assign them successive ranks.

M. Calculate the cumulative probability, P, for each GMAV as R/(N+1).

N. Select the four GMAVs which have cumulative probabilities closest to 0.05 (if there are less than 59 GMAVs, these will always be the four lowest GMAVs).

O. Using the selected GMAVs and Ps, calculate

$$S^2 = \frac{\sum((\ln GMAV)^2) - ((\sum \ln GMAV))^2 / 4}{\sum (F) - ((\sum(\sqrt{P}))^2 / 4)}$$

$$L = (\sum (\ln GMAV) - S(\sum(\sqrt{P}))) / 4$$

$$A = S(\sqrt{0.05}) + L$$

$$FAV = e^A$$

(See [11] for development of the calculation procedure and Appendix 2 for an example calculations and computer program.)

NOTE: Natural logarithms (logarithms to base e, denoted as ln) are used herein merely because they are easier to use on some hand calculators and computers than common (base 10) logarithms. Consistent use of either will produce the same result.

P. If for a commercially or recreationally important species the geometric mean of the acute values from ~~the~~ flow-through tests in which the concentrations of test material were measured is lower than the calculated Final Acute Value, then that geometric mean should be used as the Final Acute Value instead of the calculated Final Acute Value.

Q. Go to Section VI.

V. Final Acute Equation

A. When enough data are available to show that acute toxicity to two or more species is similarly related to a water quality characteristic, the relationship should be taken into account as described in Sections B-G below or using analysis of covariance [15, 16]. The two methods are equivalent and produce identical results. The manual method described below provides an understanding of this application of covariance analysis, but computerized versions of covariance analysis are much more convenient for analyzing large data sets. If two or more factors affect toxicity, multiple regression analysis should be used.

B. For each species for which comparable acute toxicity values are available at two or more different values of the water quality characteristic, perform a least squares regression of the acute toxicity values on the corresponding values of the water quality characteristic to obtain the slope and its 95% confidence limits for each species.

NOTE: Because the best documented relationship is that between hardness and acute toxicity of metals in fresh water and a log-log relationship fits these data, geometric means and natural logarithms of both toxicity and water quality are used in the rest of this section. For relationships based on other water quality characteristics, such as pH, temperature, or salinity, no transformation or a different transformation might fit the data better, and appropriate changes will be necessary throughout this section.

C. Decide whether the data for each species is useful, taking into account the range and number of the tested values of the water quality characteristic and the degree of agreement within and between species. For example, a slope based on six data points might be of limited value if it is based only on data for a very narrow range of values of the water quality characteristic. A slope based on only two data points, however, might be useful if it is consistent with other information and if the two points cover a broad enough range of the water quality characteristic. In addition, acute values that appear to be questionable in comparison with other acute and chronic data available for the same species and for other species in the same genus probably should not be used. For example, if after adjustment for the water quality characteristic, the acute values available for a species or genus differ by more than a factor of 10, rejection of some or all of the values is probably appropriate. If useful slopes are not available for at least one fish and one invertebrate or if the available slopes are too dissimilar or if too few data are available to adequately define the relationship between acute toxicity and the water quality characteristic, return to Section IV.G., using the results of tests

conducted under conditions and in waters similar to those commonly used for toxicity tests with the species.

D. Individually for each species calculate the geometric mean of the available acute values and then divide each of the acute values for a species by the mean for the species. This normalizes the acute values so that the geometric mean of the normalized values for each species individually and for any combination of species is 1.0.

E. Similarly normalize the values of the water quality characteristic for each species individually.

F. Individually for each species perform a least squares regression of the normalized acute toxicity values on the corresponding normalized values of the water quality characteristic. The resulting slopes and 95% confidence limits will be identical to those obtained in Section B above. Now, however, if the data are actually plotted, the line of best fit for each individual species will go through the point 1,1 in the center of the graph.

G. Treat all the normalized data as if they were all for the same species and perform a least squares regression of all the normalized acute values on the corresponding normalized values of the water quality characteristic to obtain the pooled acute slope, V, and its 95% confidence limits. If all the normalized data are actually plotted, the line of best fit will go through the point 1,1 in the center of the graph.

H. For each species calculate the geometric mean, W, of the acute toxicity values and the geometric mean, X, of the values of the water quality characteristic. (These were calculated in steps D and E above.)

I. For each species calculate the logarithm, Y, of the SMAV at a selected value, Z, of the water quality characteristic using the equation:

$$Y = \ln W - V(\ln X - \ln Z).$$

J. For each species calculate the SMAV at Z using the equation: $SMAV = e^{Y}$.

NOTE: Alternatively, the SMAVs at Z can be obtained by skipping step H above, using the equations in steps I and J to adjust each acute value individually to Z, and then calculating the geometric mean of the adjusted values for each species individually. This alternative procedure allows an examination of the range of the adjusted acute values for each species.

K. Obtain the Final Acute Value at Z by using the procedure described in Section IV.J-O.

L. If the SMAV at Z of a commercially or recreationally important species is lower than the calculated Final Acute Value at Z, then that SMAV should be used as the Final Acute Value at Z instead of the calculated Final Acute Value.

M. The Final Acute Equation is written as: Final Acute Value = $e^{(V[\ln(\text{water quality characteristic})] + \ln A - V[\ln Z])}$, where V = pooled acute slope and A = Final Acute Value at Z. Because

V, A, and Z are known, the Final Acute Value can be calculated for any selected value of the water quality characteristic.

VI. Final Chronic Value

A. Depending on the data that are available concerning chronic toxicity to aquatic animals, the Final Chronic Value might be calculated in the same manner as the Final Acute Value or by dividing the Final Acute Value by the Final Acute-Chronic Ratio. In some cases it may not be possible to calculate a Final Chronic Value.

NOTE: As the name implies, the acute-chronic ration (ARC) is a way of relating acute and chronic toxicities. The acute-chronic ratio is basically the inverse of the application factor, but this new name is better because it is more descriptive and should help prevent confusion between "application factors" and "safety factors". Acute-chronic ratios and application factors are ways of relating the acute and chronic toxicities of a material to aquatic organisms. Safety factors are used to provide an extra margin of safety beyond the known or estimated sensitivities of aquatic organisms. Another advantage of the acute-chronic ratio is that it will usually be greater than one; this should avoid the confusion as to whether a large application factor is one that is close to unity or one that has a denominator that is much greater than the numerator.

B. Chronic values should be based on results of flow-through (except renewal is acceptable for daphnids) chronic tests in which the concentrations of test material in the test solutions were properly measured at appropriate times during the test.

C. Results of chronic tests in which survival, growth, or reproduction in the control treatment was unacceptably low should not be used. The limits of acceptability will depend on the species.

D. Results of chronic tests conducted in unusual dilution water, e.g., dilution water in which total organic carbon or particulate matter exceeded 5 mg/L, should not be used, unless a relationship is developed between chronic toxicity and organic carbon or particulate matter or unless data show that organic carbon, particulate matter, etc., do not affect toxicity.

E. Chronic values should be based on endpoints and lengths of exposure appropriate to the species. Therefore, only results of the following kinds of chronic toxicity tests should be used:

1. Life-cycle toxicity tests consisting of exposures of each of two or more groups of individuals of a species to a different concentration of the test material throughout a life cycle. To ensure that all life stages and life processes are exposed, tests with fish should begin with embryos or newly hatched young less than 48 hours old, continue through maturation and reproduction, and should end not less than 24 days (90 days for salmonids) after the hatching of the next generation. Tests with daphnids should begin with young less than 24 hours old and last for not less than 21 days. Tests with mysids should begin with young less than 24 hours old and continue until 7 days past the median time of first brood release in the

controls. For fish, data should be obtained and analyzed on survival and growth of adults and young, maturation of males and females, eggs spawned per female, embryo viability (salmonids only), and hatchability. For daphnids, data should be obtained and analyzed on survival and young per female. For mysids, data should be obtained and analyzed on survival, growth, and young per female.

2. Partial life-cycle toxicity tests consisting of exposures of each of two or more groups of individuals of a species of fish to a different concentration of the test material through most portions of a life cycle. Partial life-cycle tests are allowed with fish species that require more than a year to reach sexual maturity, so that all major life stages can be exposed to the test material in less than 15 months. Exposure to the test material should begin with immature juveniles at least 2 months prior to active gonad development, continue through maturation and reproduction, and end not less than 24 days (90 days for salmonids) after the hatching of the next generation. Data should be obtained and analyzed on survival and growth of adults and young, maturation of males and females, eggs spawned per female, embryo viability (salmonids only), and hatchability.

3. Early life-stage toxicity tests consisting of 28- to 32-day (60 days post hatch for salmonids) exposures of the early life stages of a species of fish from shortly after fertilization through embryonic, larval, and early juvenile development. Data should be obtained and analyzed on survival and growth.

   NOTE: Results of an early life-stage test are used as predictions of results of life-cycle and partial life-cycle tests with the same species. Therefore, when results of a life-cycle or partial life-cycle test are available, results of an early life-stage test with the same species should not be used. Also, results of early life-stage tests in which the incidence of mortalities or abnormalities increased substantially near the end of the test should not be used because results of such tests are possibly not good predictions of the results of comparable life-cycle or partial life-cycle tests.

F. A chronic value may be obtained by calculating the geometric mean of the lower and upper chronic limits from a chronic test or by analyzing chronic data using regression analysis. A lower chronic limit is the highest tested concentration (a) in an acceptable chronic test, (b) which did not cause an unacceptable amount of adverse effect on any of the specified biological measurements, and (c) below which no tested concentration caused an unacceptable effect. An upper chronic limit is the lowest tested concentration (a) in an acceptable chronic test, (b) which did cause an unacceptable amount of adverse effect on one or more of the specified biological measurements, and (c) above which all tested concentrations also caused such an effect.

   NOTE: Because various authors have used a variety of terms and definitions to interpret and report results of chronic tests, reported results should be reviewed carefully. The amount of effect that is considered unacceptable is often based on a statistical hypothesis test, but might also be defined in terms of a specified percent reduction from the controls. A small percent reduction (e.g., 3%) might be

considered acceptable even if it is statistically significantly different from the control, whereas a large percent reduction (e.g., 30%) might be considered unacceptable even if it is not statistically significant.

G. If the chronic toxicity of the material to aquatic animals apparently has been shown to be related to a water quality characteristic such as hardness or particulate matter for freshwater animals or salinity or particulate matter for saltwater animals, a Final Chronic Equation should be derived based on that water quality characteristic. Go to Section VII.

H. If chronic values are available for species in eight families as described in Sections III.B.1 or III.C.1, a Species Mean Chronic Value (SMCV) should be calculated for each species for which at least one chronic value is available by calculating the geometric mean of all chronic values available for the species, and appropriate Genus Mean Chronic Values should be calculated. The Final Chronic Value should then be obtained using the procedure described in Section IV.J-O. Then go to Section VI.M.

I. For each chronic value for which at least one corresponding appropriate acute value is available, calculate an acute-chronic ratio, using for the numerator the geometric mean of the results of all acceptable flow-through (except static is acceptable for daphnids) acute tests in the same dilution water and in which the concentrations were measured. For fish, the acute test(s) should have been conducted with juveniles. The acute test(s) should have been part of the same study as the chronic test. If acute tests were not conducted as part of the same study, acute tests conducted in the same laboratory and dilution water, but in a different study, may be used. If no such acute tests are available, results of acute tests conducted in the same dilution water in a different laboratory may be used. If no such acute tests are available, an acute-chronic ratio should not be calculated.

J. For each species, calculate the species mean acute-chronic ratio as the geometric mean of all acute-chronic ratios available for that species.

K. For some materials the acute-chronic ratio seems to be the same for all species, but for other materials the ratio seems to increase or decrease as the Species Mean Acute Value (SMAV) increases. Thus the Final Acute-Chronic Ratio can be obtained in four ways, depending on the data available:

1. If the species mean acute-chronic ratio~~s~~ seems to increase or decrease as the SMAV increases, the Final Acute-Chronic Ratio should be calculated as the geometric mean of the acute-chronic ratios for species whose SMAVs are close to the Final Acute Value.

2. If no major trend is apparent and the acute-chronic ratios for a number of species are within a factor of ten, the Final Acute-Chronic Ratio should be calculated as the geometric mean of all the species mean acute-chronic ratios available for both freshwater and saltwater species.

3. For acute tests conducted on metals and possibly other substances with embryos and larvae of barnacles, bivalve molluscs, sea urchins, lobsters,

crabs, shrimp, and abalones (see Section IV.E.2), it is probably appropriate to assume that the acute-chronic ratio is 2. Chronic tests are very difficult to conduct with most such species, but it is likely that the sensitivities of embryos and larvae would determine the results of life-cycle tests. Thus, if the lowest available SMAVs were determined with embryos and larvae of such species, the Final Acute-Chronic Ratio should probably be assumed to be 2, so that the Final Chronic Value is equal to the Criterion Maximum Concentration (see Section XI.B).

4. If the most appropriate species mean acute-chronic ratios are less than 2.0, and especially if they are less than 1.0, acclimation has probably occurred during the chronic test. Because continuous exposure and acclimation cannot be assured to provide adequate protection in field situations, the Final Acute-Chronic Ratio should be assumed to be 2, so that the Final Chronic Value is equal to the Criterion Maximum Concentration (see Section XI.B).

If the available species mean acute-chronic ratios do not fit one of these cases, a Final Acute-Chronic Ratio probably cannot be obtained, and a Final Chronic Value probably cannot be calculated.

L. Calculate the Final Chronic Value by dividing the Final Acute Value by the Final Acute-Chronic Ratio. If there was a Final Acute Equation rather than a Final Acute Value, see also Section VII.A.

M. If the Species Mean Chronic Value of a commercially or recreationally important species is lower than the calculated Final Chronic Value, then that Species Mean Chronic Value should be used as the Final Chronic Value instead of the calculated Final Chronic Value.

N. Go to Section VIII.

VII. Final Chronic Equation

A. A Final Chronic Equation can be derived in two ways. The procedure described here in Section A will result in the chronic slope being the same as the acute slope. The procedure described in Sections B-N will usually result in the chronic slope being different from the actual slope.

1. If acute-chronic ratios are available for enough species at enough values of the water quality characteristic to indicate that the acute-chronic ratio is probably the same for all species and is probably independent of the water quality characteristic, calculate the Final Acute-Chronic Ratio as the geometric mean of the available species mean acute-chronic ratios.

2. Calculate the Final Chronic Value at the selected value Z of the water quality characteristic by dividing the Final Acute Value at Z (see Section V.M.) by the Final Acute-Chronic Ratio.

3. Use V = pooled acute slope (see section V.M.) as L = pooled chronic slope.

4. Go to Section VII.M.

B. When enough data are available to show that chronic toxicity to at least one species is related to a water quality characteristic, the relationship should be taken into account as described in Sections B-G below or using analysis of covariance [15, 16]. The two methods are equivalent and produce identical results. The manual method described below provides an understanding of this application of covariance analysis, but computerized versions of covariance analysis are much more convenient for analyzing large data sets. If two more factors affect toxicity, multiple regression analysis should be used.

C. For each species for which comparable chronic toxicity values are available at two or more different values of the water quality characteristic, perform a least squares regression of the chronic toxicity values on the corresponding values of the water quality characteristic to obtain the slope and its 95% confidence limits for each species.

NOTE: Because the best documented relationship is that between hardness and acute toxicity of metals in fresh water and a log-log relationship fits these data, geometric means and natural logarithms of both toxicity and water quality are used in the rest of this section. For relationships based on other water quality characteristics, such as pH, temperature, or salinity, no transformation or a different transformation might fit the data better, and appropriate changes will be necessary throughout this section. It is probably preferable, but not necessary, to use the same transformation that was used with the acute values in Section V.

D. Decide whether the data for each species is useful, taking into account the range and number of the tested values of the water quality characteristic and the degree of agreement within and between species. For example, a slope based on six data points might be of limited value if it is based only on data for a very narrow range of values of the water quality characteristic. A slope based on only two data points, however, might be useful if it is consistent with other information and if the two points cover a broad enough range of the water quality characteristic. In addition, chronic values that appear to be questionable in comparison with other acute and chronic data available for the same species and for other species in the same genus probably should not be used. For example, if after adjustment for the water quality characteristic, the chronic values available for a species or genus differ by more than a factor of 10, rejection of some or all of the values is probably appropriate. If a useful chronic slope is not available for at least one species or if the available slopes are too dissimilar or if too few data are available to adequately define the relationship between chronic toxicity and the water quality characteristic, it might be appropriate to assume that the chronic slope is the same as the acute slope, which is equivalent to assuming that the acute-chronic ratio is independent of the water quality characteristic. Alternatively, return to Section VI.H, using the results of tests

conducted under conditions and in waters similar to those commonly used for toxicity tests with the species.

E. Individually for each species calculate the geometric mean of the available chronic values and then divide each chronic value for a species by the mean for the species. This normalizes the chronic values so that the geometric mean of the normalized values for each species individually and for any combination of species is 1.0.

F. Similarly normalize the values of the water quality characteristic for each species individually.

G. Individually for each species perform a least squares regression of the normalized chronic toxicity values on the corresponding normalized values of the water quality characteristic. The resulting slopes and the 95% confidence limits will be identical to those obtained in Section B above. Now, however, if the data are actually plotted, the line of best fit for each individual species will go through the point 1,1 in the center of the graph.

H. Treat all the normalized data as if they were all for the same species and perform a least squares regression of all the normalized chronic values on the corresponding normalized values of the water quality characteristic to obtain the pooled chronic slope, L, and its 95% confidence limits. If all the normalized data are actually plotted, the line of best fit will go through the point 1,1 in the center of the graph.

I. For each species calculate the geometric mean, M, of the toxicity values and the geometric mean, P, of the values of the water quality characteristic. (These were calculated in steps E and F above.)

J. For each species calculated the logarithm, Q, of the Species Mean Chronic Value at a selected value, Z, of the water quality characteristic using the equation: $Q = \ln M - L(\ln P - \ln Z)$.

NOTE: Although it is not necessary, it will usually be best to use the same value of the water quality characteristic here as was used in Section V.I.

K. For each species calculate a Species Mean Chronic Value at Z using the equation: $SMCV = e^{Q}$.

NOTE: Alternatively, the Species Mean Chronic Values at Z can be obtained by skipping step J above, using the equations in steps J and K to adjust each acute value individually to Z and then calculating the geometric means of the adjusted values for each species individually. This alternative procedure allows an examination of the range of the adjusted chronic values for each species.

L. Obtain the Final Chronic Value at Z by using the procedure described in Section IV.J-O.

M. If the Species Mean Chronic Value at Z of a commercially or recreationally important species is lower than the calculated Final Chronic Value at Z, then that Species Mean

N. The Final Chronic Equation is written as: Final Chronic Value = $e^{(L[\ln(\text{water quality characteristic})] + \ln S - L[\ln Z])}$, where L = pooled chronic slope and S = Final Chronic Value at Z. Because L, S and Z are known, the Final Chronic Value can be calculated for any selected value of the water quality characteristic.

VIII. Final Plant Value

A. Appropriate measures of the toxicity of the material to aquatic plants are used to compare the relative sensitivities of aquatic plants and animals. Although procedures for conducting and interpreting the results of toxicity tests with plants are not well developed, results of tests with plants usually indicate that criteria which adequately protect aquatic animals and their uses will probably also protect aquatic plants and their uses.

B. A plant value is the result of a 96-hr test conducted with an alga or a chronic test conducted with an aquatic vascular plant.

NOTE: A test of the toxicity of a metal to a plant usually should not be used if the medium contained an excessive amount of a complexing agent, such as EDTA, that might affect the toxicity of the metal. Concentrations of EDTA above about 200 µg/L should probably be considered excessive.

C. The Final Plant Value should be obtained by selecting the lowest result from a test with an important aquatic plant species in which the concentrations of test material were measured and the endpoint was biologically important.

IX. Final Residue Value

A. The Final Residue Value is intended to (a) prevent concentrations in commercially or recreationally important aquatic species from affecting marketability because of exceedance of applicable FDA action levels and (b) protect wildlife, including fishes and birds, that consume aquatic organisms from demonstrated unacceptable effects. The Final Residue Value is the lowest of the residue values that are obtained by dividing maximum permissible tissue concentrations by appropriate bioconcentration or bioaccumulation factors. A maximum permissible tissue concentration is either (a) an FDA action level [12] for fish oil or for the edible portion of fish or shellfish, or (b) a maximum acceptable dietary intake based on observations on survival, growth, or reproduction in a chronic wildlife feeding study or a long-term wildlife field study. If no maximum permissible tissue concentration is available, go to Section X because no Final Residue Value can be derived.

B. Bioconcentration factors (BCFs) and bioaccumulation factors (BAFs) are quotients of the concentration of a material in one or more tissues of an aquatic organism divided by the average concentration in the solution in which the organism had been living. A BCF is intended to account only for net uptake directly from water, and thus almost

has to be measured in a laboratory test. Some uptake during the bioconcentration test might not be directly from water if the food sorbs some of the test material before it is eaten by the test organisms. A BAF is intended to account for the net uptake from both food and water in a real-world situation. A BAF almost has to be measured in a field situation in which predators accumulate the material directly from water and by consuming prey that itself could have accumulated the material from both food and water. The BCF and BAF are probably similar for a material with a low BCF, but the BAF is probably higher than the BCF for materials with high BCFs. Although BCFs are not too difficult to determine, very few BAFs have been measured acceptably because it is necessary to make enough measurements of the concentration of the material in water to show that it was reasonably constant for a long enough period of time over the range of territory inhabited by the organisms. Because so few acceptable BAFs are available, only BCFs will be discussed further. However, if an acceptable BAF is available for a material, it should be used instead of any available BCFs.

C. If a maximum permissible tissue concentration is available for a substance (e.g., parent material, parent material plus metabolites, etc.), the tissue concentration used in the calculation of the BCF should be for the same substance. Otherwise~~,~~ the tissue concentration used in the calculation of the BCF should be that of the material and its metabolites which are structurally similar and are not much more soluble in water than the parent material.

D.

1. A BCF should be used only if the test was flow-through, the BCF was calculated based on measured concentrations of the test material in tissue and in the test solution, and the exposure continued at least until either apparent steady-state or 28 days was reached. Steady-state is reached when the BCF does not change significantly over a period of time, such as two days or 16 percent of the length of the exposure, whichever is longer. The BCF used from a test should be the highest of (a) the apparent steady-state BCF, if apparent steady-state was reached, (b) the highest BCF obtained, if apparent steady-state was not reached, and (c) the projected steady-state BCF, if calculated.

2. Whenever a BCF is determined for a lipophilic material, the percent lipids should also be determined in the tissue(s) for which the BCF was calculated.

3. A BCF obtained from an exposure that adversely affected the test organisms may be used only if it is similar to a BCF obtained with unaffected organisms of the same species at lower concentrations that did not cause adverse effects.

4. Because maximum permissible tissue concentrations are almost never based on dry weights, a BCF calculated using dry tissue weights must be converted to a wet tissue weight basis. If no conversion factor is reported with the BCF, multiply the dry weight BCF by 0.1 for plankton and by 0.2 for individual species of fishes and invertebrates [17].

5. If more than one acceptable BCF is available for a species, the geometric mean of the available values should be used, except that if the BCFs are from different lengths of exposure and the BCF increases with length of exposure, the BCF for the longest exposure should be used.

E. If enough pertinent data exist, several residue values can be calculated by dividing maximum permissible tissue concentrations by appropriate BCFs:

1. For each available maximum acceptable dietary intake derived from a chronic feeding study or a long-term field study with wildlife, including birds and aquatic organisms, the appropriate BCF is based on the whole body of aquatic species which constitute or represent a major portion of the diet of the tested wildlife species.

2. For an FDA action level for fish or shellfish, the appropriate BCF is the highest geometric mean species BCF for the edible portion (muscle for decapods, muscle with or without skin for fishes, adductor muscle for scallops, and total soft tissue for other bivalve molluscs) of a consumed species. The highest species BCF is used because FDA action levels are applied on a species-by-species basis.

F. For lipophilic materials, it might be possible to calculate additional residue values. Because the steady-state BCF for a lipophilic material seems to be proportional to percent lipids from one tissue to another and from one species to another [18, 19, 20], extrapolations can be made from tested tissues or species to untested tissues or species on the basis of percent lipids.

1. For each BCF for which the percent lipids is known for the same tissue for which the BCF was measured, normalize the BCF to a one percent lipid basis by dividing the BCF by the percent lipids. This adjustment to a one percent lipid basis is intended to make all the measured BCFs for a material comparable regardless of the species or tissue with which the BCF was measured.

2. Calculate the geometric mean normalized BCF. Data for both saltwater and freshwater species should be used to determine the mean normalized BCF, unless the data show that the normalized BCFs are probably not similar.

3. Calculate all possible residue values by dividing the available maximum permissible tissue concentrations by the mean normalized BCF and by the percent lipids values appropriate to the maximum permissible tissue concentrations, i.e.,

$$\text{Residue Value} = \frac{(\text{maximum permissible tissue concentration})}{(\text{mean normalized BCF})\,(\text{appropriate percent lipids})}$$

a. For an FDA action level for fish oil, the appropriate percent lipids value is 100.

b. For an FDA action level for fish, the appropriate percent lipids value is 11 for freshwater criteria and 10 for saltwater criteria because FDA action levels are applied on a species-by-species basis to commonly consumed species. The highest lipid contents in the edible portions of important consumed species are about 11 percent for both the freshwater chinook salmon and lake trout and about 10 percent for the saltwater Atlantic herring [21].

c. For a maximum acceptable dietary intake derived from a chronic feeding study or a long-term field study with wildlife, the appropriate percent lipids is that of an aquatic species or group of aquatic species which constitute a major portion of the diet of the wildlife species.

G. The Final Residue Value is obtained by selecting the lowest of the available residue values.

NOTE: In some cases the Final Residue Value will not be low enough. For example, a residue value calculated from an FDA action level will probably result in an average concentration in the edible portion of a fatty species that is at the action level. Some individual organisms, and possibly some species, will have residue concentrations higher than the mean value but no mechanism has been devised to provide appropriate additional protection. Also, some chronic feeding studies and long-term field studies with wildlife identify concentrations that cause adverse effects but do not identify concentrations which do not cause adverse effects; again no mechanism has been devised to provide appropriate additional protection. These are some of the species and uses that are not protected at all times in all places.

X. Other Data

Pertinent information that could not be used in earlier sections might be available concerning adverse effects on aquatic organisms and their uses. The most important of these are data on cumulative and delayed toxicity, flavor impairment, reduction in survival, growth, or reproduction, or any other adverse effect that has been shown to be biologically important. Especially important are data for species for which no other data are available. Data from behavioral, biochemical, physiological, microcosm, and field studies might also be available. Data might be available from tests conducted in unusual dilution water (see IV.D and VI.D), from chronic tests in which the concentrations were not measured (see VI.B), from tests with previously exposed organisms (see II.F), and from tests on formulated mixtures or emulsifiable concentrates (see II.D). Such data might affect a criterion if the data were obtained with an important species, the test concentrations were measured, and the endpoint was biologically important.

XI. Criterion

A. A criterion consists of two concentrations: the Criterion Maximum Concentration and the Criterion Continuous Concentration.

B. The Criterion Maximum Concentration (CMC) is equal to one-half the Final Acute Value.

C. The Criterion Continuous Concentration (CCC) is equal to the lowest of the Final Chronic Value, the Final Plant Value, and the Final Residue Value, unless other data (see Section X) show that a lower value should be used. If toxicity is related to a water quality characteristic, the CCC is obtained from the Final Chronic Equation, the Final Plant Value, and the Final Residue Value by selecting the one, or the combination, that results in the lowest concentrations in the usual range of the water quality characteristic, unless other data (see Section X) show that a lower value should be used.

D. Round [14] both the CMC and the CCC to two significant digits.

E. The criterion is stated as:

The procedures described in the "Guidelines for Deriving Numerical National Water Quality Criteria for the Protection of Aquatic Organisms and Their Uses" indicate that, except possibly where a locally important species is very sensitive, (1) aquatic organisms and their uses should not be affected unacceptably if the four-day average concentration of (2) does not exceed (3) μg/L more than once every three years on the average and if the one-hour average concentration does not exceed (4) μg/L more than once every three years on the average.

where (1) = insert "freshwater" or "saltwater"

(2) = insert name of material

(3) = insert the Criterion Continuous Concentration

(4) = insert the Criterion Maximum Concentration.

XII. Final Review

A. The derivation of the criterion should be carefully reviewed by rechecking each step of the Guidelines. Items that should be especially checked are:

1. If unpublished data are used, are they well documented?
2. Are all required data available?
3. Is the range of acute values for any species greater than a factor of 10?
4. Is the range of Species Mean Acute Values for any genus greater than a factor of 10?
5. Is there more than a factor of ten difference between the four lowest Genus Mean Acute Values?
6. Are any of the four lowest Genus Mean Acute Values questionable?

7. Is the Final Acute Value reasonable in comparison with the Species Mean Acute Values and Genus Mean Acute Values?

8. For any commercially or recreationally important species, is the geometric mean of the acute values from flow-through tests in which the concentrations of test material were measured lower than the Final Acute Value?

9. Are any of the chronic values questionable?

10. Are chronic values available for acutely sensitive species?

11. Is the range of acute-chronic ratios greater than a factor of 10?

12. Is the Final Chronic Value reasonable in comparison with the available acute and chronic data?

13. Is the measured or predicted chronic value for any commercially or recreationally important species below the Final Chronic Value?

14. Are any of the other data important?

15. Do any data look like they might be outliers?

16. Are there any deviations from the Guidelines? Are they acceptable?

B. On the basis of all available pertinent laboratory and field information, determine if the criterion is consistent with sound scientific evidence. If it is not, another criterion, either higher or lower, should be derived using appropriate modifications of these Guidelines.

Appendix 1. Resident North American Species of Aquatic Animals Used in Toxicity and Bioconcentation Tests

Introduction

These lists identify species of aquatic animals which have reproducing wild populations in North America and have been used in toxicity or bioconcentration tests. "North America" includes only the 48 contiguous states, Canada, and Alaska; Hawaii and Puerto Rico are not included. Saltwater (i.e., estuarine and true marine) species are considered resident in North America if they inhabit or regularly enter shore waters on or above the continental shelf to a depth of 200 meters. Species do not have to be native to be resident. Unlisted species should be considered resident North American species if they can be similarly confirmed or if the test organisms were obtained from a wild population in North America.

The sequence for fishes is taken from A List of Common and Scientific Names of Fishes from the United States and Canada. For other species, the sequence of phyla, classes, and families is taken from the NODC Taxonomic Code, Third Edition, National Oceanographic Data Center, NOAA, Washington, DC 20235, July, 1981, and the numbers given are from that source to facilitate verification. Within a family, genera are in alphabetical order, as are species in a genus.

The references given are those used to confirm that the species is a resident North American species. (The NODC Taxonomic Code contains foreign as well as North American species.) If no such reference could be found, the species was judged to be nonresident. No reference is given for organisms not identified to species; these are considered resident only if obtained from wild North American populations. A few nonresident species are listed in brackets and noted as "nonresident" because they were mistakenly identified as resident in the past or to save other investigators from doing literature searches on the same species.

Special Note

This December 2010 electronic version of the 1985 Guidelines serves to meet the requirements of Section 508 of the Rehabilitation Act. While converting the 1985 Guidelines to a 508-compliant version, EPA updated the taxonomic nomenclature to reflect changes that occurred since the tables were originally produced in 1985. The numbers included for Phylum, Class and Family represent those currently in use from the Integrated Taxonomic Information System, or ITIS, and reflect what is referred to in ITIS as Taxonomic Serial Numbers. ITIS replaced the National Oceanographic Data Center (NODC) taxonomic coding system which was used to create the original taxonomic tables included in the 1985 Guidelines document (NODC, Third Addition - see Introduction). For more information on the NODC taxonomic codes, see http://www.nodc.noaa.gov/General/CDR-detdesc/taxonomic-v8.html.

The code numbers included in the reference column of the tables have not been updated from the 1985 version. These code numbers are associated with the old NODC taxonomic referencing system and are simply replicated here for historical purposes. Footnotes may or may not still apply.

EPA is working on a more comprehensive update to the 1985 Guidelines, including new taxonomic tables which better reflect the large number of aquatic animal species known to be propagating in U.S. waters.

Freshwater Species Table

Synonyms appear after the official Scientific Name and are marked with an asterisk (*).
Non-resident species are noted in the Reference column and are marked with a dagger (†)

Footnotes for Freshwater Species

[1] Apparently this is an outdated name (D19, 20). Organisms identified as such should only be used if they were obtained from North America.

[2] Apparently this is an outdated name (D19, 20). Organisms identified as such should only be used if they were obtained from North America.

[3] If from North America, it is resident and should be called *D. similis* (C). If not from North America, it should be considered nonresident.

[4] If from North America, it is resident and may be any one of a number of species such as *D. laevie, D. dubia,* or *D. galeate mendoca* (C). If not from North America, it should be considered nonresident.

[5] If from North America, it is resident and may be any one of a number of species such as *D. ambigua*, *D. longiremis*, or *D. rosea* (C). If not from North America, it should be considered nonresident.

[6] This species might be established in portions of the southern United States.

[7] The taxonomy of this species and this and similar genera has not been clarified, but this species should be considered resident.

Saltwater Species Table

Synonyms appear after the official Scientific Name and are marked with an asterisk (*).
Non-resident species are noted in the Reference column and are marked with a dagger (†)

Class	Family	Species		Reference
		Common Name	Scientific Name	
Phylum: Cnidaria (Coelenterata) (48738)				
Hydroza 48739	Campanulariidae 49470	Hydroid	*Campanularia flexiosa* *Campanularia flexuosa***	B122, E81
		Hydroid	*Laomedea loveni*††	nonresident
		Hydromedusa	*Phialidium sp.*	[1] (E81)
	Campanulinidae 49756	Hydroid	*Eirene viridula*†	nonresident
Phylum: Ctenophora (53856)				
Tentaculata 53858	Pleurobrachiidae 53860	Ctenophore	*Pleurobrachia pileus*	B218, E162
	Mnemiidae 53915	Ctenophore	*Mnemiopsis mccradyi*	C39, I94
Phylum: Nemertea (Rhynchocoela) (57411)				
Heteronemertea 57438	Lineidae 57443	Nemertine worm	*Cerebratulus fuscus*	B252
Phylum: Rotifera (Rotatoria) (58239)				
Monogononta 58342	Brachionidae 58344	Rotifer	*Brachionus plicatilis*	B272
Phylum: Annelida (64357)				
Polychaeta 64358	Phyllodocidae 65228	Polychaete worm	*Phyllodoce maculata* *Anaitides maculata** *Nereiphylla maculata**	E334
	Nereididae (Nereidae) 65870	Polychaete worm	*Neanthes arenaceodentata* *Nereis arenaceodentata**	E377
		Polychaete worm	*Neanthes vaali*†	nonresident
		Polychaete worm	*Nereis diversicolor* *Neanthes diversicolor**	E337, F527
		Sand worm	*Nereis virens* *Neanthes virens**	B317, E337, C58
		Polychaete worm	*Nereis sp.*	
	Dorvilleidae 66478	Polychaete worm	*Ophryotrocha diadema*	P23
		Polychaete worm	*Ophryotrocha labronica*† *Ophryotrocha labrunica**†	nonresident
	Spionidae 66781	Polychaete worm	*Polydora websteri*	E338
	Cirratulidae 67116	Polychaete worm	*Cirriformia spirabranchia*	G253
	Ctenodrilidae 67217	Polychaete worm	*Ctenodrilus serratus*	G275
	Capitellidae 67413	Polychaete worm	*Capitella capitata*	B358, E337
	Arenicolidae 67500	Polychaete worm	*Arenicola marina*	B369, E337

** Synonym
†† Non-resident species

Class	Family	Species		Reference
		Common Name	Scientific Name	
	Sabellidae 68076	Polycheate worm	*Eudistylia vancouveri*	DD
Oligochaeta 68422	Tubificidae 68585	Oligochaete worm	*Limnodriloides verrucosus*	Z
		Oligochaete worm	*Monopylephorus cuticulatus*	Z
		Oligochaete worm	*Peloscolex gabriellae* *Tubificoides gabriellae*[*]	Z
Phylum: Mollusca (69458)				
Gastropoda 69459	Haliotididae 566897	Black abalone	*Haliotis cracherodii*	C88, D17
		Red abalone	*Haliotis rufescens*	D18
	Calyptraeidae 72611	Common Atlantic slippershell	*Crepidula fornicata*	C90, D141
	Muricidae 73236	Oyster drill	*Urosalpinx cinerea* *Urosalpinx cinereus*[*]	B646, D179, E264
	Melongenidae (Neptuneidae) 74069	Channeled whelk	*Busycotypus canaliculatus* *(Formerly Busycon canaliculatum)*	B655, D223, E264
	Nassariidae (Nassidae) 74102	Mud snail	*Nassarius obsoletus* *Nassa obsoleta*[*] *Icyanassa obsoleta*[*]	B649, D226, E264
Bivalvia (Pelecypoda) 79118	Mytilidae 79451	Northern horse mussel	*Modiolus modiolus*	D434
		Blue mussel	*Mytilus edulis*	B566, C101, D428, E299
		Mediterranean mussel	*Mytilus galloprovincialis*[†]	nonresident
	Pectinidae 79611	Bay scallop	*Argopecten irradians*	D447
	Ostreidae 79866	Pacific oyster	*Crassostrea gigas*	C102, D456, E300
		Eastern oyster	*Crassostrea virginica*	D456, E300
		Oyster	*Crassostrea sp.*	1
		Oyster	*Ostrea edulis*	E300
	Cardiidae 80865	Cockle	*Cerastoderma edule*[†] *Cardium edule*[*†]	nonresident
	Mactridae 80942	Clam	*Mulinia lateralis*	D491
		Common rangia	*Rangia cuneata*	D491, E301
		Surf clam	*Spisula solidissima*	B599, D489, E301
	Tellinidae 81032	Clam	*Macoma inquinata*	D507
		Bivalve	*Tellina tenuis*[†]	nonresident
	Veneridae 81439	Quahog clam	*Mercenaria mercenaria*	D523, E301
		Common Pacific littleneck	*Protothaca staminea*	D526
		Japanese littleneck clam	*Tapes philippinarum*	D527
	Myidae 81688	Soft-shell clam	*Mya arenaria*	B602, D536, E302
Phylum: Arthropoda (82696)				
Merostomata 82698	Limulidae 82701	Horseshoe crab	*Limulus polyphemus*	B533, E403, H30
Branchiopoda (Formerly Crustacea) 83687	Artemiidae 83689	Brine shrimp	*Artemia salina*[†]	[2] nonresident
Maxillopoda (Formerly Crustacea) 621145	Calanidae 85259	Copepod	*Calanus helgolandicus*	Q25
		Copepod	*Undinula vulgaris*	Q29
	Eucalanidae 85299	Copepod	*Eucalanus elongatus*	AA
		Copepod	*Subeucalanus pileatus* *Eucalanus pileatus*[*]	AA
	Pseudocalanidae 85351	Copepod	*Pseudocalanus minutus*	E447, I155, Q43

Class	Family	Species		Reference
		Common Name	Scientific Name	
	Euchaetidae 85524	Copepod	*Euchaeta marina*	Q63
	Metridinidae (Formerly Metridiidae) 593501	Copepod	*Metridia pacifica*	X179, Y
	Pseudodiaptomidae 85847	Copepod	*Pseudodiaptomus coronatus*	E447, I154, Q101
	Temoridae 85855	Copepod	*Eurytemora affinis*	E450, I155, Q111
	Pontellidae 86038	Copepod	*Labidocera scotti*	R157
	Acartiidae 86083	Copepod	*Acartia clausi*	E447
		Copepod	*Acartia tonsa*	E447, I154
	Harpacticidae 86329	Copepod	*Tigriopus californicus*	J78
		Copepod	*Tigriopus japanicus*†	nonresident
	Tisbidae 86444	Copepod	*Tisbe holothuriae*	BB
	Ameiridae (Formerly Canthocamptidae) 86999	Copepod	*Nitokra spinipes* *Nitocra spinipe**	Q240
	Archaeobalanidae (Formerly Balanidae) 89681	Barnacle	*Semibalanus balanoides* *Balanus balanoides**	B424, E457
	Balanidae 89599	Barnacle	*Balanus crenatus*	B426, E457
		Barnacle	*Balanus eburneus*	B424, E457
		Barnacle	*Balanus improvisus*	B426, E457
Malacostraca (Formerly Crustacea) 89787	Mysidae 89856	Mysid	*Heteromysis formosa*	E513, K720
		Mysid	*Americamysis bahia* *Mysidopsis bahia**	U173
		Mysid	*Americamysis bigelowi* *Mysidopsis bigelowi**	E513, K720
		Mysid	*Neomysis sp.*	1
	Idoteidae 92564	Isopod	*Idotea balthica* *Idothea baltica**	B446, E483
		Isopod	*Idotea emarginata*†	nonresident
		Isopod	*Idotea neglecta*†	nonresident
	Janiridae 92810	Isopod	*Jaera albifrons*†	nonresident
		Isopod	*Jaera albifrons sensu*†	nonresident
		Isopod	*Jaera nordmanni*†	nonresident
	Ampeliscidae 93320	Amphipod	*Ampelisca abdita*	E488, L136
	Eusiridae (Pontogeneiidae) 93681	Amphipod	*Pontogeneia sp.*	1
	Gammaridae 93745	Amphipod	*Gammarus duebeni*	L56
		Amphipod	*Gammarus oceanicus*	E489, L50
		Amphipod	*Gammarus tigrinus*	L51
		Amphipod	*Gammarus zaddachi*†	nonresident
		Amphipod	*Marinogammarus obtusatus*	L58
	Uristadae (Formerly Lysianassidae) 621432	Amphipod	*Anonyx sp.*	1
	Euphausiidae (Thysanopodidae) 95500	Euphausiid	*Euphausia pacifica*	M15
	Penaeidae	Brown shrimp	*Penaeus aztecus*	E518, N17

Class	Family	Species		Reference
		Common Name	Scientific Name	
	95602	Pink shrimp	*Penaeus duorarum*	E518, N17
		White shrimp	*Penaeus setiferus*	E518, N17
		Blue Shrimp	*Penaeus stylirostris*†	nonresident
	Palaemonidae 96213	Shrimp	*Leander paucidens*†	nonresident
		Prawn	*Leander squilla*† *Palaemon elegans**†	nonresident
		Prawn	*Macrobrachium rosenbergii*	[3]
		Korean shrimp	*Palaemon macrodactylus*	T380
		Grass shrimp	*Palaemonetes pugio*	E521, N59
		Grass shrimp	*Palaemonetes vulgaris*	B500, E521, N56
	Hippolytidae 96746	Sargassum shrimp	*Latreutes fucorum*	N78
	Pandalidae 96965	Coon stripe shrimp	*Pandalus danae*	T306, W163
		Shrimp	*Pandalus goniurus*	W163
		Pink shrimp	*Pandalus montagui*	B494, E522, W163
	Crangonidae 97106	Sand shrimp	*Crangon crangon*†	nonresident
		Bay shrimp	*Crangon franciscorum* *Crago franciscorum**	V176, W164
		Shrimp	*Crangon nigricauda*	V176, W164
		Sand shrimp	*Crangon septemspinosa*	B500, E522
	Nephropidae (Homaridae) 97307	American lobster	*Homarus americanus*	B502, E532
		European lobster	*Homarus gammarus*†	nonresident
	Paguridae 97774	Hermit crab	*Pagurus longicarpus*	B514, E537, N125
	Cancridae 98670	Rock crab	*Cancer irroratus*	B518, E543, N175
		Dungeness crab	*Cancer magister*	T166, V185, W177
	Portunidae 98689	Blue crab	*Callinectes sapidus*	B521, C80, E543, N168
		Green crab	*Carcinus maenas*	C80, E543
	Xanthidae (Pilumnidae) 98748	Mud crab	*Eurypanopeus depressus*	B522, E543, N195
		Crab	*Leptodius floridanus*	S80
		Mud crab	*Rhithropanopeus harrisii*	E543, N187
	Varunidae (formerly Grapsidae) 621521	Shore crab	*Hemigrapsus nudus*	CC
		Shore crab	*Hemigrapsus oregonensis*	CC
	Sesarmidae (formerly Grapsidae) 621520	Drift line crab	*Armases cinereum* *(Sesarma cinereum)*	B526, E544, N222
		Crab	*Sesarma haematocheir*†	nonresident
	Ocypodidae 99080	Fiddler crab	*Uca pugilator*	B526, E544, N232
Phylum: Echinodermata (156857)				
Asteroidea 156862	Asteriidae 157212	Starfish	*Asterias forbesi*	B728, E578, O392
Ophiuroidea 157325	Ophiothricidae 157792	Brittle star	*Ophiothrix spiculata*	O672, T526
Echinoidea 157821	Arbaciidae 157904	Sea urchin	*Arbacia lixula*†	nonresident
		Sea urchin	*Arbacia punctulata*	B762, E572
	Toxopneustidae 157919	Sea urchin	*Lytechinus pictus*	T253
		Sea urchin	*Pseudocentrotus depressus*†	nonresident
	Echinidae 157940	[chinoderm	*Paracentrotus lividus*†	nonresident
	Echinometridae 157955	Coral reef echinoid	*Echinometra mathaei*†	nonresident [Hawaii only]

Class	Family	Species		Reference
		Common Name	Scientific Name	
	Strongylocentrotidae 157965	Sea urchin	*Strongylocentrotus purpuratus*	O574, T202
	Dendrasteridae 158008	Sand dollar	*Dendraster excentricus*	O537, V363
Phylum: Chaetognatha (158650)				
Sagittoidea 158655	Sagittidae 158726	Arrow worm	*Ferosagitta hispida* *Sagitta hispida*[*]	E218
Phylum: Chordata (158852)				
Chondrichthyes 159785	Rajidae 160845	Thornback ray	*Raja clavata*[†]	nonresident
Actinopterygii (Formerly Osteichthyes) 161061	Anguillidae 161125	American eel	*Anguilla rostrata*	A15
	Clupeidae 161700	Atlantic menhaden	*Brevoortia tyrannus*	A17
		Gulf menhaden	*Brevoortia patronus*	A17
		Atlantic herring	*Clupea harengus* *Clupea harengus harengus*[*]	A17
		Pacific herring	*Clupea pallasii* *Clupea harengus pallasii*[*]	A17
		Herring	*Clupea harengus*	A17
	Engraulidae 553173	Northern anchovy	*Engraulis mordax*	A18
		Nehu	*Encrasicholina purpurea*[†] *tolephorus purpureus*[*†]	nonresident [Hawaii only]
	Salmonidae 161931	Pink salmon	*Oncorhynchus gorbuscha*	A18
		Chum salmon	*Oncorhynchus keta*	A18
		Coho salmon	*Oncorhynchus kisutch*	A18
		Sockeye salmon	*Oncorhynchus nerka*	A19
		Chinook salmon	*Oncorhynchus tshawytscha*	A19
		Rainbow trout (Steelhead trout)	*Oncorhynchus mykiss* (Formerly *Salmo gairdneri)*	A19
		Atlantic salmon	*Salmo salar*	A19
	Gadidae 164701	Atlantic cod	*Gadus morhua*	A30
		Haddock	*Melanogrammus aeglefinus*	A30
	Cyprinodontidae 165629	Sheepshead minnow	*Cyprinodon variegatus*	A33
		Mummichog	*Fundulus heteroclitus*	A33
		Striped killifish	*Fundulus majalis*	A33
		Longnose killifish	*Fundulus similis*	A33
	Poeciliidae 165876	Mosquitofish	*Gambusia affinis*	A33
		Sailfin molly	*Poecilia latipinna*	A34
	Atherinidae 165984	Inland silverside	*Menidia beryllina*	A34
		Atlantic silverside	*Menidia menidia*	A34
		Tidewater silverside	*Menidia peninsulae*	A34
	Gasterosteidae 166363	Threespine stickleback	*Gasterosteus aculeatus*	A35
		Fourspine stickleback	*Apeltes quadracus*	A35
	Syngnathidae 166443	Northern pipefish	*Syngnathus fuscus*	A36
	Percichthyidae 170315	Striped bass	*Morone saxatilis* (*Roccus saxatilis,* Obs.*)*	A36
	Kuhliidae 168083	Mountain bass	*Kuhlia sandvicensis*[†]	nonresident [Hawaii only]
	Carangidae 168584	Florida Pompano	*Trachinotus carolinus*	A43

Class	Family	Species		Reference
		Common Name	Scientific Name	
	Sparidae 169180	Pinfish	*Lagodon rhomboides*	A45
	Sciaenidae 169237	Spot	*Leiostomus xanthurus*	A46
		Atlantic croaker	*Micropogonias undulatus*	A46
		Red drum	*Sciaenops ocellatus*	A46
	Embiotocidae 169735	Shiner perch	*Cymatogaster aggregata*	A47
		Dwarf perch	*Micrometrus minimus*	A48
	Pomacentridae 170044	Blacksmith	*Chromis punctipinnis*	A48
	Labridae 170477	Cunner	*Tautogolabrus adspersus*	A49
		Bluehead	*Thalassoma bifasciatum*	A49
	Mugilidae 170333	Mullet	*Aldrichetta forsteri*†	nonresident
		Striped mullet	*Mugil cephalus*	A49
		White mullet	*Mugil curema*	A49
	Ammodytidae 171670	Pacific sand lance	*Ammodytes hexapterus*	A53
	Gobiidae 171746	Longjaw mudsucker	*Gillichthys mirabilis*	A54
		Naked goby	*Gobiosoma bosci*	A54
	Cottidae 167196	Tidepool sculpin	*Oligocottus maculosus*	A61
	Bothidae 172714	Speckled sanddab	*Citharichthys stigmaeus*	A64
		Summer Flounder	*Paralichthys dentatus*	A64
	Pleuronectidae 172859	Dab	*Limanda limanda*†	nonresident
		Plaice	*Pleuronectes platessa*†	nonresident
		English sole	*Parophrys vetulus*	A65
		Winter flounder	*Pseudopleuronectes americanus*	A65
	Balistidae 173128	Planehead filefish	*Monacanthus hispidus*	A66
	Tetraodontidae 173283	Northern puffer	*Sphoeroides maculatus*	A66

Footnotes for Saltwater Species

[1] Organisms not identified to species are considered resident only if obtained from wild populations in North America.

[2] This species should not be used because it might be too atypical.

[3] This species might be established in portions of the southern United States.

Appendix 2. Example Calculation of Final Acute Value, Computer Program, and Printouts

A. Example Calculation

N = total number of MAVs in data set = 8

Rank	MAV	ln(MAV)	$\ln(MAV)^2$	P = R / (N+1)	$\sqrt{P}$
4	6.4	1.8563	3.4458	0.44444	0.66667
3	6.2	1.8245	3.3290	0.33333	0.57735
2	4.8	1.5686	2.4606	0.22222	0.47140
1	0.4	-0.9163	0.8396	0.11111	0.33333
Sum		4.3331	10.0750	1.11110	2.04875

$$S^2 = \frac{10.0750 - (4.3331)^2 / 4}{1.11110 - (2.04875)^2 / 4} = 87.134$$

$S = 9.3346$

$L = [\ 4.3331 - (9.3346)(2.04875)] / 4 = -3.6978$

$A = (9.3346)\ (\sqrt{0.05}\ ) - 3.6978 = -1.6105$

$FAV = e^{-1.6105} = 0.1998$

B. Example Computer Program in BASIC Language for Calculating the FAV

```
10    REM This program calculates the FAV when there are less than
20    REM 59 MAVs in the data set
30    X = 0
40    X2 = 0
50    Y = 0
60    Y2 = 0
70    PRINT "How many MAVs are in the data set?"
80    INPUT N
90    PRINT "What are the four lowest MAVs?"
100   FOR R = 1 TO 4
110         INPUT V
```

```
120         X = X + LOG(V)
130         X2 = X2 + (LOG(V)) * (LOG(V))
140         P = R / (N + 1)
150         Y2 = Y2 + P
160         Y = Y + SQR((X2 – X * X / 4))
170   NEXT R
180   S = SQR((X2 – X * X / 4) / (Y2 – Y * Y / 4))
190   L = (X – S * Y) / 4
200   A = S * SQR(0.05) + L
210   F = EXP(A)
220   PRINT "FAV = " F
230   END
```

C. Example Printouts from Program

```
How many MAVs are in the data set?
? 8
What are the four lowest MAVs?
? 6.4
? 6.2
? 4.8
? .4
FAV = 0.1998

How many MAVs are in the data set?
? 16
What are the four lowest MAVs?
? 6.4
? 6.2
? 4.8
? .4
FAV = 0.4365
```

[1]With adequate pretreatment (filtration & disinfection) and natural quality to meet drinking water standards.

[2]See also Figures 310A and 310B for fish use designations for this basin. Note: The fish & aquatic life use designations for the "constructed channel" segment of the West Division Main Canal in this table supersede Figure 310A, which incorrectly identifies Redband trout use in that portion of the canal.

[3]The West Division Main Canal extends from the point of diversion from the Umatilla River to the confluence with the Columbia River. The canal consists of two segments. The constructed channel segment extends from the Umatilla River 27 miles down gradient to the flow control gate at the end of the concrete structure as it was originally built (concrete-lining was later added to parts of the overflow channels). The overflow channels segment extends from the lower end of the constructed channel to the outflow to the Columbia River.

Table 30
Aquatic Life Water Quality Criteria for Toxic Pollutants

The concentration for each compound listed in Table 30 is a criterion established for waters of the state in order to protect aquatic life. The aquatic life criteria apply to waterbodies where the protection of fish and aquatic life is a designated use. All values are expressed as micrograms per liter (µg/L). Compounds are listed in alphabetical order with the corresponding information: the Chemical Abstract Service (CAS) number, whether there is a human health criterion for the pollutant (i.e. "y"= yes, "n" = no), and the associated aquatic life freshwater and saltwater acute and chronic criteria. *Italicized* pollutants are not identified as priority pollutants by EPA. Dashes in the table column indicate that there is no aquatic life criterion.

Unless otherwise noted in the table below, the acute criterion is the Criterion Maximum Concentration (CMC) applied as a one-hour average concentration, and the chronic criterion is the Criterion Continuous Concentration (CCC) applied as a 96-hour (4 days) average concentration. The CMC and CCC criteria may not be exceeded more than once every three years. Footnote A, associated with eleven pesticide pollutants in Table 30, describes the exception to the frequency and duration of the toxics criteria stated in this paragraph.

OAR 340-041-8033
Table 30
Aquatic Life Water Quality Criteria for Toxic Pollutants

				Acute Criterion (CMC)	Chronic Criterion (CCC)	Acute Criterion (CMC)	Chronic Criterion (CCC)
3	*Ammonia*	7664417	n	*The ammonia criteria are pH and temperature dependent — See ammonia criteria Tables 30(a)-(c) at end of Table 30.*[M]		*The ammonia criteria are pH, temperature and salinity dependent. Values for saltwater criteria (total ammonia) can be calculated from the tables specified in Ambient Water Quality Criteria for Ammonia (Saltwater)—1989 (EPA 440/5-88-004) See DEQ's calculator for calculating saltwater ammonia criteria at: http://www.deq.state.or.us/wq/standards/toxics.htm*	
[M] *The acute criteria in Table 30(a) apply in waterbodies where salmonids are a designated use in OAR 340-041-0101 through OAR 340-041-0340. The acute criteria in Table 30(b) apply in waterbodies where salmonids are not a designated use. The chronic criteria in Table 30(c) apply where fish and aquatic life is a designated use. It is not necessary to account for the presence or absence of salmonids or the presence of any early life stage of fish for the chronic criteria. Refer to DEQ's beneficial use website at: http://www.deq.state.or.us/wq/standards/uses.htm for additional information on salmonid beneficial use designations, including tables and maps.*

Expanded Endnotes A, E, F, N

Endnote A: Alternate Frequency and Duration for Certain Pesticides

This criterion is based on EPA recommendations issued in 1980 that were derived using guidelines that differed from EPA's 1985 Guidelines which update minimum data requirements and derivation procedures. The CMC may not be exceeded at any time and the CCC may not be exceeded based on a 24-hour average. The CMC may be applied using a one hour averaging period not to be exceeded more than once every three years, if the CMC values given in Table 30 are divided by 2 to obtain a value that is more comparable to a CMC derived using the 1985 Guidelines.

Endnote E: Equation for Hardness-Dependent Freshwater Cadmium Acute Criteria

The freshwater criterion for this metal is expressed as total recoverable with two significant figures, and is a function of hardness (mg/L) in the water column. Criteria values based on hardness are calculated using the following formula (CMC refers to the acute criterion):

$$\mathbf{CMC} = (\exp(m_A*[\ln(\text{hardness})] + b_A))$$

Chemical	m_A	b_A	m_C	b_C
Cadmium	1.128	-3.828	N/A	N/A

Endnote F: Equations for Hardness-Dependent Freshwater Metals Criteria and Conversion Factor Table

The freshwater criterion for this metal is expressed as dissolved with two significant figures, and is a function of hardness (mg/L) in the water column. Criteria values based on hardness are calculated using the following formulas (CMC refers to the acute criterion; CCC refers to the chronic criterion):

$$\textbf{CMC} = (\exp(m_A*[\ln(\text{hardness})] + b_A))*CF$$

$$\textbf{CCC} = (\exp(m_C*[\ln(\text{hardness})] + b_C))*CF$$

"CF" is the conversion factor used for converting a metal criterion expressed as the total recoverable fraction in the water column to a criterion expressed as the dissolved fraction in the water column.

Values for Calculating Hardness-Dependent Metals Criteria				
Chemical	**m_A**	**b_A**	**m_C**	**b_C**

Lead	1.273	-1.460	1.273	-4.705
Nickel	0.8460	2.255	0.8460	0.0584
Silver	1.72	-6.59	--	--
Zinc	0.8473	0.884	0.8473	0.884

The conversion factors (CF) below must be used in the equations above for the hardness-dependent metals in order to convert total recoverable metals criteria to dissolved metals criteria. For metals that are not hardness-dependent (i.e. arsenic, chromium VI, selenium, and silver (chronic)), or are saltwater criteria, the criterion value associated with the metal in Table 30 already reflects a dissolved criterion based on its conversion factor below.

Conversion Factor (CF) Table for Dissolved Metals				
Chemical	Freshwater		Saltwater	
	Acute	Chronic	Acute	Chronic
Arsenic	1.000	1.000	1.000	1.000
Cadmium	N/A	1.101672-[(ln hardness)(0.041838)]	0.994	0.994
Chromium III	0.316	0.860	--	--
Chromium VI	0.982	0.962	0.993	0.993
Copper	N/A	N/A	0.83	0.83
Lead	1.46203-[(ln hardness)(0.145712)]	1.46203-[(ln hardness)(0.145712)]	0.951	0.951
Nickel	0.998	0.997	0.990	0.990
Selenium	0.996	0.922	0.998	0.998
Silver	0.85	0.85	0.85	--
Zinc	0.978	0.986	0.946	0.946

Endnote N: Deriving freshwater copper criteria

The freshwater copper criteria at any time are the Biotic Ligand Model (BLM) derived Instantaneous Water Quality Criteria (IWQC) output based on a concurrently measured set of model input parameter values. The Biotic Ligand Model uses multiple ambient water quality parameters to derive 1-hour acute exposure (CMC) and 96-hour chronic exposure (CCC) water quality criteria (IWQC) for copper based on the site specific water chemistry that determines the toxicity of copper to aquatic life. If measured data for one or more of the model input parameters used to derive the acute and chronic IWQC is not available, the procedures in section (1) or (2) of this endnote will be used as specified to substitute an estimate or a default value for the missing input parameter. BLM results (IWQC) based on sufficient measured input parameter data are more accurate and supersede results based on estimates or default values. The acceptable BLM software to calculate the IWQC include version 2.2.3, referenced in "Aquatic Life Ambient Freshwater Quality Criteria – Copper": EPA-822-R-07-001, February 2007, and version 2.2.4. The criteria are expressed as dissolved copper in micrograms per liter (to the nearest one-tenth).

(1) Input Parameter Substitution and Estimation Procedures to Derive BLM Criteria (IWQC)

If the measured value for any input parameter needed to derive an IWQC using the BLM is not available, DEQ will substitute an estimated input parameter value according to the procedures described in this section [Endnote N (1)]. If the data required to determine the estimated parameter value is not available, DEQ will use default values derived according to the procedures in Endnote N (2).

(a) Total recoverable concentration measurements will be substituted for dissolved concentration measurements that are not available. For alkalinity, calcium, chloride, magnesium, potassium, sodium and sulfate, total recoverable concentration measurements will be used as a direct substitute for dissolved concentration measurements. Total organic carbon (TOC) measurements will be multiplied by 0.83 to convert the TOC value to an equivalent dissolved organic carbon (DOC) value; except where sufficient TOC and DOC data are available for a site, DEQ will calculate and apply a site-specific translator in place of 0.83 to convert TOC values to DOC for use in the BLM.

(b) Alkalinity, calcium, chloride, magnesium, potassium, sodium and sulfate:
If data for any of these BLM input parameters are missing from a particular dataset, DEQ will estimate its value based on the relationship of the ion or alkalinity to specific conductance measurements for that data set using the regression analysis equations in Table 1. Specific conductance measurements must be concurrent with the other BLM input parameters dataset.

Table N-1	
Parameter	**Regression Equation**
Alkalinity	$Alk. = \exp^{(0.88 \cdot [\ln(SpC)] - 0.41)}$
Calcium	$Ca = \exp^{(0.96 \cdot [\ln(SpC)] - 2.29)}$
Chloride	$Cl = \exp^{(1.15 \cdot [\ln(SpC)] - 3.82)}$
Magnesium	$Mg = \exp^{(0.91 \cdot [\ln(SpC)] - 3.09)}$
Potassium	$K = \exp^{(0.84 \cdot [\ln(SpC)] - 3.74)}$
Sodium	$Na = \exp^{(0.86 \cdot [\ln(SpC)] - 2.22)}$
Sulfate	$SO_4 = \exp^{(1.45 \cdot [\ln(SpC)] - 5.59}$

Where, "SpC" is a measurement of specific conductance in μmhos/cm, "ln" is the natural logarithm, and "exp" is a mathematical constant that is the base of the natural logarithm.

(c) pH
If concurrent pH data is missing from the sample dataset, DEQ will use a representative pH value determined by interpolating from data available for the site or proximate monitoring locations where conditions (such as type of water body, stream flow and geology) are similar to the site. DEQ will use the available data and methods to produce the best practicable estimate of pH for the site and time for which the IWQC is being derived.

(d) Temperature
If concurrent temperature data is missing from the sample dataset, DEQ will use a monthly mean temperature based on data available for the site or proximate monitoring locations where conditions (such as type of water body and stream flow) are similar to the site.

(e) Humic Acid
If sufficient high quality data on the percentage of humic acid as a proportion of DOC is available for a site, DEQ will use that value in the BLM in place of the default value of 10% used in the model.

(2) Default Action Values

If the measured value for DOC, alkalinity, calcium, chloride, magnesium, potassium, sodium or sulfate is not available to derive an IWQC using the BLM, and the parameter value cannot be estimated as specified in section (1) above, DEQ will use a conservative input value for the missing parameter as described in this section [Endnote N (2)] to derive a default action value using the Biotic Ligand Model. The default action value will be used for Clean Water Act purposes until measured or estimated input parameter data are available to derive accurate copper criteria (IWQC) based on site specific water chemistry.

(a) The default input parameter values for DOC, alkalinity calcium, chloride, magnesium, potassium, sodium and sulfate will be the percentile value from the distribution of the high quality data available for surface waters in the region as shown in Table N-2.

Table N-2
Percentile of data distribution to be used as default value by region

Region	DOC percentile	Alkalinity and Ions percentile
Willamette	20th	20th
Coastal	20th	20th
Cascades	20th	20th
Eastern	15th	15th
Columbia River	20th	20th

(b) The regional default values for each parameter and region will be updated periodically as additional high quality data becomes available and is added to DEQ's database.
(c) The regional default values for each parameter are available on DEQ's website.
(d) The regions listed in Table N-2 are comprised of the following EPA Level III ecoregions or waterbody:
(i) Willamette: the Willamette Valley
(ii) Coastal: Coast Range and Klamath Mountains
(iii) Cascades: Cascades
(iv) Eastern: Eastern Cascades Slopes and Foothills, Columbia Plateau, Blue Mountains, Northern Basin and Range and Snake River Plain
(v) Columbia River: Columbia River mainstem in Oregon

(3) General Policies
(a) The copper BLM derives instantaneous criteria results (IWQC) that vary at a site over time reflecting the effect of local water chemistry on copper toxicity to aquatic organisms. DEQ will apply the BLM criteria for Clean Water Act purposes to protect the water body during the most bioavailable or toxic conditions.
(b) For assessing waters of the state, DEQ will use approaches that give preference to the use of BLM criteria derived with site-specific measured input parameter data.

Table 30(a): Ammonia Acute Criteria Values (One-hour Average)—Salmonid Species Present
Temperature and pH-Dependent and expressed as Total Ammonia Nitrogen (mg/L TAN)

Criteria cannot be exceeded more than once every three years

$$Acute\ Criterion = MIN\left(\left(\frac{0.275}{1+10^{7.204-pH}}+\frac{39.0}{1+10^{pH-7.204}}\right),\left(0.7249\times\left(\frac{0.0114}{1+10^{7.204-pH}}+\frac{1.6181}{1+10^{pH-7.204}}\right)\times\left(23.12\times 10^{0.036\times(20-T)}\right)\right)\right)$$

TABLE 31
Aquatic Life Water Quality Guidance Values for Toxic Pollutants

Effective April 18, 2014

Water Quality Guidance Values Summary [A]

The concentration for each compound listed in Table 31 is a guidance value that DEQ may use in application of Oregon's Toxic Substances Narrative (340-041-0033(2)) to waters of the state in order to protect aquatic life. All values are expressed as micrograms per liter (µg/L) except where noted. Compounds are listed in alphabetical order with the corresponding EPA number (from National Recommended Water Quality Criteria: 2002, EPA-822-R-02-047), corresponding Chemical Abstract Service (CAS) number, aquatic life freshwater acute and chronic guidance values, and aquatic life saltwater acute and chronic guidance values.

The following chemicals/compounds/classes are of concern due to the potential for toxic effects to aquatic organisms; however, no guidance values are designated. If these compounds are identified in the waste stream, then a review of the scientific literature may be appropriate for deriving guidance values.

- Polybrominated diphenyl ethers (PBDE)
- Polybrominated biphenyls (PBB)
- Pharmaceuticals
- Personal care products
- Alkyl Phenols
- Other chemicals with Toxic effects

Footnotes:

A Values in Table 31 are applicable to all basins.

B This number was assigned to the list of non-priority pollutants in National Recommended Water Quality Criteria: 2002 (EPA-822-R-02-047).

OAR 340-041-8033
TABLE 40
Human Health Water Quality Criteria for Toxic Pollutants

Effective April 18, 2014

Human Health Criteria Summary

The concentration for each pollutant listed in Table 40 was derived to protect Oregonians from potential adverse health impacts associated with long-term exposure to toxic substances associated with consumption of fish, shellfish, and water. The "organism only" criteria are established to protect fish and shellfish consumption and apply to waters of the state designated for fishing. The "water + organism" criteria are established to protect the consumption of drinking water, fish, and shellfish, and apply where both fishing and domestic water supply (public and private) are designated uses. All criteria are expressed as micrograms per liter (µg/L), unless otherwise noted. Pollutants are listed in alphabetical order. Additional information includes the Chemical Abstract Service (CAS) number, whether the criterion is based on carcinogenic effects (can cause cancer in humans), and whether there is an aquatic life criterion for the pollutant (i.e. "y"= yes, "n" = no). All the human health criteria were calculated using a fish consumption rate of 175 grams per day unless otherwise noted. A fish consumption rate of 175 grams per day is approximately equal to 23 8-ounce fish meals per month. For pollutants categorized as carcinogens, values represent a cancer risk of one additional case of cancer in one million people (i.e. 10^{-6}), unless otherwise noted. All metals criteria are for total metal concentration, unless otherwise noted. Italicized pollutants represent non-priority pollutants. The human health criteria revisions established by OAR 340-041-0033 and shown in Table 40 do not become applicable for purposes of ORS chapter 468B or the federal Clean Water Act until approved by EPA pursuant to 40 CFR 131.21 (4/27/2000).

OAR 340-041-8033
Table 40
Human Health Water Quality Criteria for Toxic Pollutants

No.	Pollutant	CAS Number	Carcinogen	Aquatic Life Criterion	Human Health Criteria for the Consumption of:	
					Water + Organism (µg/L)	Organism Only (µg/L)
1	Acenaphthene	83329	n	n	95	99
2	Acrolein	107028	n	n	0.88	0.93
3	Acrylonitrile	107131	y	n	0.018	0.025
4	Aldrin	309002	y	y	0.0000050	0.0000050
5	Anthracene	120127	n	n	2900	4000
6	Antimony	7440360	n	n	5.1	64
7	Arsenic (inorganic) [A]	7440382	y	y	2.1	2.1(freshwater) 1.0 (saltwater)
[A] *The arsenic criteria are expressed as total inorganic arsenic. The "organism only" freshwater criterion is based on a risk level of approximately 1 x 10^{-5}, and the "water + organism" criterion is based on a risk level of 1 x 10^{-4}.*						
8	Asbestos [B]	1332214	y	n	7,000,000 fibers/L	--
[B] *The human health risks from asbestos are primarily from drinking water, therefore no "organism only" criterion was developed. The "water + organism" criterion is based on the Maximum Contaminant Level (MCL) established under the Safe Drinking Water Act.*						
9	*Barium* [C]	7440393	n	n	1000	--
[C] *The human health criterion for barium is the same as originally published in the 1976 EPA Red Book which predates the 1980 methodology and did not utilize the fish ingestion BCF approach. This same criterion value was also published in the 1986 EPA Gold Book. Human health risks are primarily from drinking water, therefore no "organism only" criterion was developed. The "water + organism" criterion is based on the Maximum Contaminant Level (MCL) established under the Safe Drinking Water Act.*

16. ABSTRACT

This document recommends and describes a design for landfill covers that will meet the requirements of RCRA regulations. It is a multilayered system consisting, from the top down, of:

- a top layer of at least 60 cm of soil, either vegetated or armored at the surface;
- a granular or geosynthetic drainage layer with a hydraulic transmissivity no less than 3×10^{-5} cm^2/sec; and
- a two-component low permeability layer comprised of (1) a flexible membrane liner installed directly on (2) a compacted soil component with an hydraulic conductivity no greater than 1×10^{-7} cm/sec.

Optional layers may be added, e.g., a biotic barrier layer or a gas vent layer, depending on the need.

DISCLAIMER

The preparation of this document has been funded wholly by the United States Environmental Protection Agency. It has been subjected to the Agency's peer and admininistrative review, and it has been approved for publication as an EPA document. Mention of trade names or commercial products does not constitute endorsement or recommendation for use.

FOREWORD

Today's rapidly developing and changing technologies and industrial products and practices frequently carry with them the increased generation of solid and hazardous wastes. These materials, if improperly dealt with, can threaten both public health and the environment. Abandoned waste sites and accidental releases of toxic and hazardous substances to the environment also have important environmental and public health implications. The Risk Reduction Engineering Laboratory assists in providing an authoritative and defensible engineering basis for assessing and solving these problems. Its products support the policies, programs, and regulations of the U.S. Environmental Protection Agency; the permitting and other responsibilities of State and local governments; and the needs of both large and small businesses in handling their wastes responsibility and economically.

This document provides design guidance on final cover systems for hazardous waste landfills and surface impoundments. We believe that the final cover, if properly designed and constructed, can provide long-term protection of the unit from moisture infiltration due to precipitation. The cover system presented herein is a multilayer design consisting of a vegetated top layer, drainage layer, and low-permeability layer. Optional layers which may be required for site-specific conditions are also discussed. Rationale is provided for the design parameters to give designers and permit writers background information and an understanding of cover systems.

This document is intended for use by organizations involved in permitting, designing, and constructing hazardous waste land disposal facilities.

E. Timothy Oppelt, Director
Risk Reduction Engineering Laboratory

PREFACE

Subtitle C of the Resource Conservation and Recovery Act (RCRA) requires the U.S. Environmental Protection Agency (EPA) to establish a Federal hazardous waste management program. This program must ensure that hazardous wastes are handled safely from generation until final disposition. EPA issued a series of hazardous waste regulations under Subtitle C of RCRA that are published in Title 40 Code of Federal Regulations (40 CFR). The principal 40 CFR Part 264 and 265 regulations were issued on July 26, 1982 for treatment, storage, and disposal (TSD) facilities and establish performance standards for hazardous waste landfills, surface impoundments, land treatment units, and waste piles. The regulations have been amended several times since then.

In support of the regulations, EPA has been developing three types of documents to assist preparers and reviewers of RCRA permit applications for hazardous waste TSD facilities. These include RCRA Technical Guidance Documents, Permit Guidance Manuals, and Technical Resource Documents (TRDs).

RCRA Technical Guidance Documents, such as this one, present design and operating parameters or design evaluation techniques that generally comply with, or demonstrate compliance with, the Design and Operating Requirements and the Closure and Post-Closure Requirements of 40 CFR Part 264.

The Permit Guidance Manuals are being developed to describe the permit application information the Agency seeks, and to provide guidance to applicants and permit writers in addressing information requirements. These manuals will include a discussion of each set of specifications that must be considered for inclusion in the permit.

The Technical Resource Documents present summaries of state-of-the-art technologies and evaluation techniques determined by the Agency to constitute good engineering designs, practices, and procedures. They support the RCRA Technical Guidance Documents and Permit Guidance Manuals in certain areas (i.e., liners, leachate management, final covers, and water balance) by describing current technologies and methods for designing hazardous waste facilities, or for evaluating the performance of a facility design. Although emphasis is given to hazardous waste facilities, the information presented in these TRDs may be used

for designing and operating nonhazardous waste TSD facilities as well. Whereas the RCRA Technical Guidance Documents and Permit Guidance Manuals are directly related to the regulations, the information in these TRDs covers a broader perspective and should not be used to interpret the requirements of the regulations.

This document is a Technical Guidance Document prepared by the Risk Reduction Engineering Laboratory of EPA's Office of Research and Development in cooperation with the Office of Solid Waste and Emergency Response. The document has undergone extensive technical review and has been revised accordingly. With the issuance of this document, all previous drafts are obsolete and should be discarded.

Comments are welcome at any time on the accuracy and usefulness of the information in this document. Comments will be evaluated, and suggestions will be incorporated, wherever feasible, before publication of any future revisions. Written comments should be addressed to EPA RCRA Docket (OS-305), 401 M Street S.W., Washington, DC 20460. The document for which comments are being provided should be identified by title and number.

ABSTRACT

The owner or operator of a landfill, or a surface impoundment closed as a landfill, must meet the closure requirements specified under 40 CFR 264.310 (permitted units) or 40 CFR 265.310 (interim status units).

This guidance document addresses landfill covers and recommends a multilayer final cover design that includes the following elements, from top to bottom:

- a top layer consisting of two components: (1) a vegetated or armored surface component, either of which is selected to minimize erosion and, to the extent possible, promote drainage off the cover, and (2) a soil component with a minimum thickness of 60 cm [24 in.] comprised of topsoil and/or fill soil as appropriate, the surface of which slopes uniformly at least 3 percent but not more than 5 percent;

- a soil drainage layer with a minimum thickness of 30 cm (12 in.) and a minimum hydraulic conductivity of 1×10^{-2} cm/sec that will effectively minimize water infiltration into the low-permeability layer, and a final bottom slope of at least 3 percent after settlement and subsidence; or the drainage layer may consist of geosynthetic materials with equivalent performance characteristics; the drainage layer also serves as a protective cover for the flexible membrane liner (FML) component of the underlying low-permeability layer;

- a two-component low-permeability layer, that limits water infiltration into the underlying wastes to a rate less than or equal to the rate of leachate migration out of the bottom liner system and consists of (1) a 20-mil minimum thickness [or greater depending on the material and design] FML component and (2) a 60-cm [24-inch] minimum thickness compacted soil component with an in-place saturated hydraulic conductivity no less than 1×10^{-7} cm/sec. (NOTE: The requirement for FMLs in the cover are for all permitted units and interim status units with an FML in the bottom. For interim status units with only a clay bottom liner, an FML may not be required.)

Optional layers that may be used on a site-specific basis include (1) a gas vent layer to remove gases produced within the wastes, and/or (2) a biotic barrier layer to protect the cover from animal or plant intrusion.

The Agency recommends a detailed construction quality assurance (CQA) program for each layer of the final cover system. CQA records should document quality and demonstrate compliance with plans and specifications. The cover design process must consider many site-specific factors, such as precipitation, construction materials, freeze-thaw phenomena, waste characteristics, potential subsidence, and other environmental factors.

ACKNOWLEDGMENT

The EPA Project Manager who directed the draft preparation of this document was Les Otte with the assistance of Ana Aviles, both of the Environmental Protection Agency's Office of Solid Waste, Land Disposal Branch. Early drafts of the document were prepared by David C. Anderson of K. W. Brown & Associates, Inc. Later drafts were prepared by Jeffrey D. Magaw, Charles W. Young, and Clay Spears of Alliance Technologies Corporation. This draft has been prepared by Robert P. Hartley of EPA's Risk Reduction Engineering Laboratory, after peer reviews by Dr. Gordon Boutwell of Soil Testing Engineers, Inc.; Dr. Richard C. Warner, University of Kentucky; Leo Overman of Golder Associates, Inc.; Dirk Brunner of E. C. Jordan, Inc.; the Solid and Hazardous Waste Management Committee of the American Society of Civil Engineers, Environmental Engineering Division; and by various members of the EPA's Risk Reduction Engineering Laboratory.

1. INTRODUCTION

1.1 PURPOSE

This document provides design guidance on final covers for hazardous waste units. The recommended design satisfies the requirements of 40 CFR 264 and 265 Subparts G (closure and post-closure), K (surface impoundments), and N (landfills). The Environmental Protection Agency (hereafter referred to as "the Agency") emphasizes that recommendations are guidance only and not regulations. The Agency acknowledges that other final cover designs may be acceptable, depending upon site-specific conditions and upon a determination by the Agency that an alternative design adequately fulfills the regulatory requirements. It is, however, the responsibility of the facility owner or operator to prove that the alternate design will provide a level of performance that is at least equivalent to that of the final cover system described in this document.

The Agency's liquids management strategy for landfills, and the role that final covers serve in that strategy, are outlined in general terms for background. Regulatory requirements for landfill and surface impoundment covers are also outlined, as well as differences in requirements between interim status and permitted units. The Agency-recommended final cover system design is presented in detail, as well as considerations for construction quality assurance. Attention is given to erosion, settlement, and subsidence, and their potential cover-damaging effects.

A separate section of this document is devoted to the design details of each layer of the recommended cover. A discussion of the rationale for the recommended specifications is included.

1.2 CLOSURE AND POST-CLOSURE REGULATIONS

All of the regulations dealing with hazardous waste landfill and surface impoundment cover requirements are found in Title 40, Parts 264 and 265, of the Code of Federal Regulations (40 CFR 264 and 40 CFR 265). Part 264 deals with permitted facilities and Part 265 with interim status facilities. Interim status facilities are, in general, those facilities that were in existence on November 19, 1980. Three Subparts of each of Parts 264 and 265 deal with general closure requirements: Subpart G - Closure and Post-Closure; Subpart K - Surface Impoundments; and

Subpart N - Landfills. Each Subpart contains several sections important to cover planning, design, and construction, as outlined in Table 1.

There are few difference between permitted and interim status unit closure and post-closure regulations under Subpart G of Parts 264 and 265. The major difference is that, for interim status units, public notice for changes to the approved closure and post-closure plans is not required. Changes to plans for permitted units require permit modifications which, in turn, require public notice and comment.

There are three significant differences between permitted and interim status unit final cover regulations under Subparts K and N of Parts 264 and 265. Part 264.303 requires monitoring and inspection to ensure that synthetic and soil materials used in the cover are watertight and structurally uniform. Such a requirement was not included in Part 265 for interim status units. The Agency recommends that a Construction Quality Assurance (CQA) program, establishing inspection activities, be utilized for covers being built at both permitted and interim status units. The Agency believes that a site-specific CQA inspection program is necessary to ensure that cover design specifications are met.

A second difference in requirements is that, while leachate collection and removal activities are required after closure under 40 CFR 264.310, for permitted units, they are not required under Part 265 for interim status units. The absence of a stated post-closure leachate collection and removal requirement makes cover performance for interim status units even more important. It should be noted that, under the broader performance standards of 40 CFR 265.111, the Agency may still require leachate collection during post-closure at an interim site.

The third, and perhaps most significant, difference is in the requirements of 40 CFR 264.310(b)(1)(v) and 40 CFR 265.310 (b)(1)(v). These subsections require that the cover have a permeability less than or equal to any bottom liner or natural subsoil present. For interim status units, without an engineered liner, the cover could presumably be of relatively permeable materials. But here again, the Agency may impose the standards of 40 CFR 265.111, and require a more impermeable cover.

For permitted landfills, to meet the requirements of 40 CFR 264.310, the cover must have a permeability no greater than that of the double liner required under 40 CFR 264.301(c). The Agency does not consider this to mean that the final cover for a permitted unit must actually contain a double liner. Rather, the Agency recommends that the final cover include a layer whose liquid-rejection performance is equal to or better than the

bottom composite liner (flexible membrane liner [FML] underlain, and in full contact with, compacted soil) of the double-liner system detailed in the "Minimum Technology Guidance on Double Liner Systems for Landfills and Surface Impoundments - Design, Construction and Operation" (EPA, 1987i). The Agency-recommended design for the cover does, in fact, include a composite barrier layer as outlined in Section 4. In all cases where a FML is used in the bottom liner, one should also be used in the cover. This does not mean, however, that the Agency necessarily recommends the use of exactly the same barrier materials in both the liner and cover. For example, different FML materials of equivalent performance may be used, such as high density polyethylene for the bottom liner and polyvinyl chloride in the cover.

The Agency also recommends using the composite FML/clay barrier in interim status unit covers. However, for interim status units, compacted clay with a permeability equal to or less than 1×10^{-7} cm/sec may be used without a FML if the clay is less permeable than the landfill bottom liner or natural subsoil beneath the site. While 40 CFR 265.310(a)(5) might allow a less effective design, we believe the long-term protection from infiltration provided by the recommended cover design justifies its use for all units. With the Agency-recommended composite design, it is more certain that the cover will be no more permeable than the bottom of the unit. In addition, the installation of the composite design on interim status units takes advantage of the practical opportunity to more effectively minimize water infiltration, leachate generation, and leachate migration.

1.3 LIQUIDS MANAGEMENT STRATEGY

The general closure performance standards are specified in 40 CFR 264.111 and 265.111 (Subpart G) for permitted and interim hazardous waste disposal facilities, respectively. The standards state that:

"The owner or operator must close the facility in a manner that:

a. Minimizes the need for further maintenance; and

b. Controls, minimizes, or eliminates, to the extent necessary to protect human health and the environment, post-closure escape of hazardous waste, hazardous constituents, leachate, contaminated runoff, or hazardous waste decomposition products to the ground or surface waters or to the atmosphere . . "

The requirements apply to hazardous waste landfills and to hazardous waste surface impoundments closed as landfills.

Landfill closure requirements are based on a two-part liquids management strategy of (1) minimizing the leachate generation by keeping liquids out of the unit, and (2) detecting, collecting, and removing leachate within the unit. Closure requirements are specified in 40 CFR 264.310 and 40 CFR 265.310 and include a final cover and post-closure care.

The Agency considers keeping water out of the unit to be the prime element of the strategy. Thus, the Agency believes that a properly designed and constructed cover becomes, after closure, the most important feature of the landfill structure. The Agency requires that the cover be designed and constructed to provide long-term minimization of the movement of water from the surface into the closed unit. Where the waste mass lies entirely above the zone of ground-water saturation, a properly designed and maintained cover can prevent, for all practical purposes, the entry of water into the closed unit, and thus minimize the formation and migration of leachate. In the absence of damage, the cover design recommended here, including the FML/soil low-permeability layer, should restrict infiltration, to the extent of the design, for the long term.

1.4 GENERAL COVER SYSTEM RECOMMENDATIONS

The cover system should be a major consideration during site selection, planning, and initial design of the landfill containment structure. Factors for consideration include location and availability of low-permeability soil, stockpiling of topsoil, restricting height to provide stable slopes, and site use beyond the post-closure care period.

1.4.1 Design Recommendations

The final cover recommended in this guidance document is a multilayer design (Figure 1) comprised as follows, from top to bottom:

- a top layer consisting of two components: (1) either a vegetated or armored surface component, selected to minimize erosion and, to the extent possible, promote drainage off the cover, and (2) a soil component with a minimum thickness of 60 cm [24 in.], comprised of topsoil and/or fill soil as appropriate, the surface of which slopes uniformly at least 3 percent but not more than 5 percent; a soil component of greater thickness may be required to assure that the underlying low-permeability layer is below the frost zone;

- either a soil drainage (and FML-protective bedding) layer with minimum thickness of 30 cm (12 in.) and a minimum hydraulic conductivity of 1 x 10^{-2} cm/sec that

will effectively minimize water infiltration into the low-permeability layer, and will have a final slope of at least 3 percent after settlement and subsidence; or a drainage layer consisting of geosynthetic materials with equivalent performance characteristics; and

- a two-component low-permeability layer, lying wholly below the frost zone, that provides long-term minimization of water infiltration into the underlying wastes, consisting of (1) a 20-mil [0.5 mm] minimum thickness flexible membrane liner [FML] component and (2) a compacted soil component with a minimum thickness of at least 60 cm [24 in.] and a maximum in-place saturated hydraulic conductivity of 1×10^{-7} cm/sec.

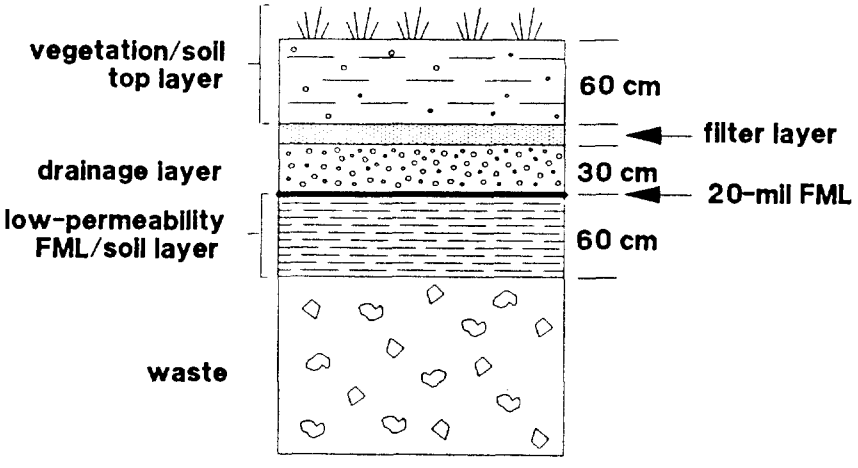

Figure 1. EPA-recommended cover design.

Optional layers may be used on a site-specific basis. Figure 2 depicts a cover design that includes optional layers. Two such layers include (1) a gas vent layer to remove gases that are produced within the wastes, and/or (2) a biotic barrier layer to protect the cover from animal or plant intrusion. Geosynthetic filter materials may also be used to prevent migration of fine materials from one layer into another or to prevent clogging of the drainage layer.

The Agency recognizes, for specific cases, that alternative designs (e.g., fewer layers or optional layers) may be applicable. For instance, in extremely arid regions, a gravel-armored top surface component might serve to compensate for a naturally reduced vegetation coverage and the erosion control that it provides. Also, in arid regions the drainage layer might not be required. In areas where burrowing animals may damage the

low-permeability layer, the damage may be prevented by use of an overlying "biotic barrier" layer of large-size material, such as cobbles. A gas vent layer between the waste and the low-permeability layer may be installed, as shown in Figure 2, at units that produce gases.

Alternative designs must provide long-term performance at least equivalent to the recommended design outlined in this guidance. All alternative designs must be approved by the appropriate Regional Administrator of the Agency.

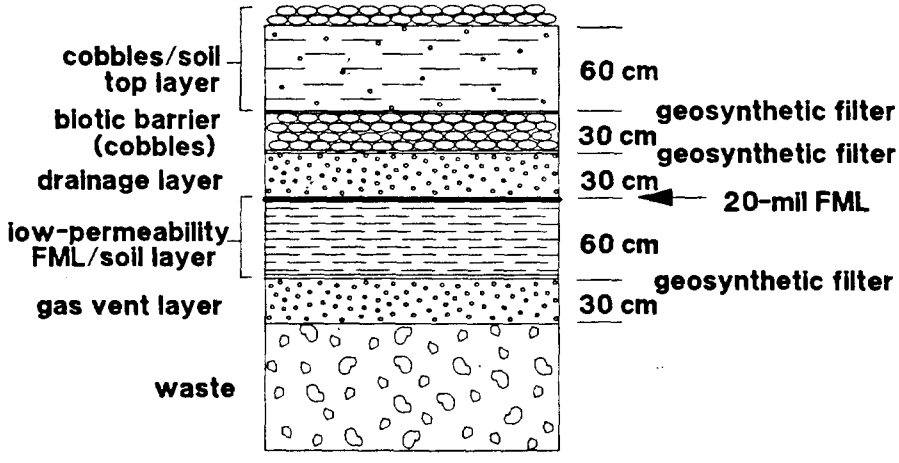

Figure 2. EPA-recommended cover design with optional layers.

In some cases, where the waste is of such character that vertical migration of gases is impeded, full-depth vent structures to the bottom of the waste mass may be needed. These structures would be designed to prevent the horizontal migration of gases out of the landfill into the surrounding soil. Active rather than passive systems may be required in some cases to adequately remove accumulated gases.

Filter layers are likely to be needed above the drainage layer and between layers that are comprised of soils of greatly different particle sizes, to prevent one from migrating into the other. The filters may be constructed of soils of intermediate grain size, or they may be geosynthetic materials. Three between-layer locations where geosynthetic filters may be appropriate are shown in Figure 2.

Table 2 presents a synopsis of the Agency-recommended components of a landfill and their principal design parameters.

1.4.2 Construction Quality Assurance (CQA)

The Agency believes that the landfill owner or operator should implement a detailed construction quality assurance (CQA) program for the final cover system based on written plans for inspecting the quality of construction materials and the construction practices employed in their placement. The Agency believes that use of a CQA program is essential for determining, with a reasonable degree of certainty, whether a completed final cover system meets or exceeds all design criteria, plans, and specifications. The Agency has issued technical guidance that includes final cover CQA (EPA, 1987i).

The Agency has proposed CQA rules for both permitted and interim status units (EPA, 1987b). These proposed rules would require a CQA program for installing the following components of landfills, surface impoundments and waste piles: foundations; low-permeability soils; FMLs; dikes; leachate detection, collection, and removal systems; and final covers. The CQA plan would be site-specific. It should address activities such as inspecting, monitoring, and sampling of the individual components. For the cover, the CQA plan should provide assurance that: 1) all layers of the final cover are uniform and damage-free; 2) the materials for each layer are as specified in the design specifications; and 3) each layer is constructed as specified in the design.

1.4.3 Settlement and Subsidence

Settlement within a closed hazardous waste landfill can disrupt the integrity and function of the final cover system. Settlement of the waste may be uniformly distributed and may occur primarily before placement of the final cover. Subsidence, however, is considered to be an unevenly distributed settlement (i.e., differential settlement) after closure that can disrupt the integrity of the final cover by creating depressions and cracks. In addition, subsidence due to the collapse of drums (this will occur mainly in older units), the leaching of soluble waste constituents, or biodegradation of organic matter in the waste, may not begin until several years after closure or it may occur gradually over decades.

To reduce the potential for damage from settlement and subsidence, the final cover should be designed and constructed to allow for the total estimated settlement. The final grade after subsidence of the cover should be at the actual desired design elevation. The cover design process used to establish the final grade elevation should include consideration of the following:

- consolidation of all waste layers (the primary consideration) and daily and intermediate soil covers;

Table 2. Synopsis of Minimum Technology Guidance for Covers

Layer	Thickness	Slope	Requirements
Top Layer			
Vegetation	--	--	Persistent, drought-resistant, adapted to local conditions.
OR			
Surface Armor	5-10 in. (13-25 cm)		Cobbles, gravel.
ON			
Soil	$\geq$ 24 in. ($\geq$ 60 cm)	3-5%	Erosion rate <2 ton/acre/yr (5.5 MT/ha/yr).
Drainage Layer			
Soil	$\geq$ 12 in. ($\geq$ 30 cm)	$\geq$ 3%	SP (USCS) soil $K > 1 \times 10^{-2}$ cm/s; gravel toe drain.
OR			
Geosynthetic	variable	$\geq$ 3%	Performance equivalent to soil, hydraulic transmissivity $\geq 3 \times 10^{-5}$ m^2/sec.
Low-Permeability Layer			
FML	$\geq$ 20 mils ($\geq$ 0.5 mm)	$\geq$ 3%	In EPA Report No. EPA 600/2-88-052.
ON			
Low-Permeability Soil	$\geq$ 24 in. ($\geq$ 60 cm)	$\geq$ 3%	In-place $K < 1 \times 10^{-7}$ cm/s and test fill.
Optional Layers (site-specific design)			
Gas Vent Layer	$\geq$ 12 in. ($\geq$ 30 cm)	$\geq$ 2%	Similar to drainage layer.
Biotic Barrier	animal or root-dependent	--	Large materials, e.g., cobbles.

- consolidation of soils and foundation materials underlying the site;
- consolidation of liner and leachate collection systems; and
- consolidation of all final cover components.

The Agency has published two technical research reports on cover settlement and subsidence (EPA, 1985c and 1987d) that address both the theoretical and practical aspects.

Interim covers have been proposed when a significant amount of settlement and subsidence is expected in a fairly short time (say 2-5 years) that could result in the premature failure of a final cover. An interim cover could be maintained until settling is judged to be virtually complete. After settlement occurs, the interim cover could be removed and replaced or overlain by a new final cover. If components of the interim cover can meet the CQA requirements for the final cover, the interim cover could be made an integral part of the final design.

In no case can an interim cover be used that does not satisfy the performance standards of 40 CFR 264.111 to protect human health and the environment. Use of an interim cover on a permitted unit will generally result in a longer closure period during which the stipulations of 40 CFR 264.113 must be met, i.e., the applicant must take all necessary steps "to prevent threats to human health and the environment from the unclosed but not operating hazardous waste management unit or facility, including compliance with all applicable permit requirements."

2. TOP LAYER

The Agency recommends a two-component top layer for a landfill cover system (Figure 1). The upper component should be vegetation or other surface treatment, designed to impede erosion but allowing surface runoff from major storm events. The Agency believes that, in most cases, vegetation underlain by soil, at least part of which is topsoil, will best accomplish these objectives. However, in some areas the prevailing climate may inhibit the establishment and maintenance of vegetation, or a planned alternative use of the site may preclude vegetation. In those cases, an armored surface without vegetation (Figure 2), and underlain by fill soil, might be used if it will minimize erosion and abrasion of the cover and allow, to the maximum practicable extent, surface drainage off the cover.

2.1 DESIGN

The Agency recommends that the vegetation component of the top layer meet the following specifications:

- Locally adapted perennial plants.
- Resistant to drought and temperature extremes.
- Roots that will not disrupt the low-permeability layer.
- Capable of thriving in low-nutrient soil with minimum nutrient addition.
- Sufficient plant density to minimize cover soil erosion to no more than 2 tons/acre/year (5.5 MT/ha/yr), calculated using the USDA Universal Soil Loss Equation.
- Capable of surviving and functioning with little or no maintenance.

In landfill situations where the environment or other considerations make it inappropriate for maintaining sufficiently dense vegetation, armoring material may be substituted as the upper component of the top layer or in rare cases the whole layer. It is recommended that the material possess the following characteristics:

- capable of remaining in place and minimizing erosion of itself and the underlying soil component during extreme weather events of rainfall and/or wind;

- capable of accommodating settlement of the underlying material without compromising the purpose of the component;

- surface slope approximately the same as the underlying soil (at least 3 percent slope); and

- capable of controlling the rate of soil erosion from the cover to no more than 2 tons/acre/year (5.5 MT/ha/yr), calculated by using the USDA Universal Soil Loss Equation.

Agency-recommended specifications for the lower soil component of the top layer include the following:

- for vegetation support, a minimum thickness of 60 cm (24 in.) including at least 15 cm (6 in.) of topsoil (soil of lower quality may be used beneath an armored surface); greater total thickness where required, e.g., where maximum frost penetration exceeds this depth, or where greater plant-available water storage is necessary or desirable;

- medium texture to facilitate seed germination and plant root development;

- final top slope, after allowance for settling and subsidence, of at least 3 percent, but no greater than 5 percent, to facilitate runoff while minimizing erosion; and

- minimum compaction to facilitate root development and sufficient infiltration to maintain growth through drier periods.

The owner or operator of the landfill should prepare a separate section specific to monitoring construction of the top layer to be included in the construction quality assurance (CQA) plan.

2.2 DISCUSSION

2.2.1 Upper Component of Top Layer

As noted in the design recommendations above, the upper component of the top layer may be vegetation (Agency-preferred where possible) or other erosion-impeding materials. These are discussed separately below.

2.2.1.1 Vegetation

Plant species is an important consideration in the establishment of vegetation when it is selected as the upper component of the top layer. The use of shrubs and trees is usually inappropriate because the root systems extend to a depth that would normally invade the drainage layer or the low-permeability layer. A large number of suitable plant species such as grasses and low-growing plants are available for various climates (EPA, 1983c and 1987c). The timing of seeding is also very important to successful vegetation establishment.

The Agency advises landfill owners or operators to contact a consulting agronomist, Cooperative Extension Service agent, or local university for recommendations of adapted plant varieties and other guidance on local crop cultivation. Several references provide lists of available vegetation and discussions on site-selection criteria (EPA, 1976, 1979, 1983a, 1983c, 1985a, and 1987c; Lee, et al., 1984; Thornburg, 1979; and Wright, 1976). These references provide essential information about plant species, seeding rate, time of seeding, and areas of adaptation.

2.2.1.2 Other Erosion-Impeding Materials

In areas where vegetation is inappropriate or difficult to establish and maintain, other materials may be selected as the upper component of the top layer. The materials should be selected to prevent erosion of the cover and yet allow, as much as practicable, for surface drainage. Several materials have been suggested for use in lieu of vegetation, including broken rock or cobbles that may prevent deterioration of the cap due to wind, heavy rain, or temperature extremes (EPA, 1982b and 1985a; Nyhan, et al., 1985; Pertusa, 1980). An example of such an upper component is a layer several (perhaps eight or more) inches thick comprised of 5- to 10-cm (2- to 4-in.) cobbles of hard durable rock. The cobbles allow infiltration of rain water but retard erosion due to water and wind action (see Figure 2). Asphalt or concrete might be used if promoting runoff is a prime objective, but they are likely to deteriorate, for example, by cracking due to thermal effects and subsidence deformation (EPA, 1979 and 1987a) thus causing concern for their long-term performance. Substantial maintenance could be expected for these materials. Asphalt can be very permeable unless special attention is given to eliminating the air voids during mixing and application (Repa, et al., 1987).

A surface armor component of very coarse materials promotes infiltration rather than runoff. Thus, it may be more applicable in arid areas. In those areas, leachate generation due to water infiltration may not be a major concern, but it can happen during infrequent short-duration storms of great intensity (EPA, 1987c).

2.2.2 Lower Component of Top Layer

When the upper component of the top layer is vegetation, the EPA recommends that the associated lower component be composed of at least 60 cm (24 in.) of soil. The soil should be capable of indefinitely sustaining plant species that will minimize erosion. The minimum thickness of the soil component is based upon the Agency's judgment that:

- it accommodates the root systems of most non-woody plant species (EPA, 1983c);
- for most locales, it provides adequate water-holding capacity to attenuate rainfall infiltration to the drainage layer and to sustain vegetation through dry periods; and
- it provides sufficient soil thickness to allow for expected long-term erosional losses.

A layer thicker than 60 cm (24 in.) may be required to prevent freezing and thawing from damaging the low-permeability layer, or to increase plant-available water storage capacity in drier climates.

Medium-textured soils such as loam soils, have the best overall characteristics for seed germination and plant root system development. Fine-textured soils, such as clays, are often fertile but may be beset by management problems such as puddling of water on the surface or difficulty in initial establishment of plant cover during wet periods. Sandy soils are often a problem due to low water retention and loss of nutrients by leaching. It may be cost-effective to stockpile the topsoil initially removed from a site for later use during cover construction. Where only a minimum amount of native topsoil can be saved by stockpiling, the remainder needed to provide at least the minimum thickness of 60 cm (24 in.) may be made up by selecting local borrow material having appropriate qualities.

The Agency recommends that the lower component of the top layer (and thus the entire top layer) be slightly convex, or be low in height above the surrounding terrain and uniformly sloped. In non-level terrain, diversion structures should be installed to prevent the run-on of surface water onto the cover. To prevent ponding of rainwater due to irregularities of the surface of the lower component, the final slope should be uniform and at least 3 percent, after allowance for settlement and subsidence (EPA, 1982a, p. 42). Slopes greater than 5 percent, however, are likely to promote erosion unless controls are included in the design. The design of surface water controls is well-documented (EPA, 1979 and 1982b). The Agency believes that slopes greater than 5 percent will increase erosion, decrease slope stability,

and, in general, increase the long-term maintenance of the cover system. Owners and operators using final slopes based on site-specific conditions should determine that the slopes will not result in the formation of erosion rills and gullies and will limit total erosion to less than 2.0 tons/acre/year (5.5 MT/ha/yr). The U.S. Department of Agriculture's Universal Soil Loss Equation (USLE) is recommended as the tool for use in evaluating erosion potential (EPA, 1982a). The Agency believes that a maximum erosion rate of 2.0 tons/acre/year (5.5 MT/ha/yr) is realistically achievable for a wide range of soils, climates, and vegetation. The Agency also believes that reliance on this criterion will minimize gully development and cover maintenance.

3. DRAINAGE LAYER

The recommended final cover design includes a drainage layer for the removal of water which infiltrates through the top layer (see Figures 3a and 3b). The drainage layer should be designed to minimize the amount and residence time of water coming into contact with the low-permeability layer, thereby decreasing the potential for leachate generation. In other words, the drainage layer construction materials and configuration should facilitate the rapid and efficient removal of water to an exit drain.

The drainage layer should be designed, constructed, and operated to function without clogging. Physical clogging may be prevented by incorporating a filter layer of soil or geosynthetic material between the top layer and the drainage layer. The prevention of biological clogging may range from limiting vegetation to shallow-rooted species to the installation of a biotic barrier (see Figure 2). Any or all of these features may be included in a single cover design.

In arid locations, the need for, and design of, a drainage layer should be based on consideration of precipitation event frequency and intensity, and sorptive capacity of other soil layers in the cover system. It may be possible to construct a top layer that will absorb most, if not all, of the precipitation that infiltrates into that layer, eliminating the need for a drainage layer.

3.1 DESIGN

If composed of granular material such as sand (Figure 3a), the Agency recommends that the cover drainage layer meet the following specifications:

- Minimum thickness of 30 cm (12 in.) and minimum slope of 3 percent at the bottom of the layer; greater thickness and/or slope if necessary to provide sufficient drainage flow as determined by site-specific hydrologic (e.g., HELP) modeling.

- Hydraulic conductivity of drainage material should be no less than 1×10^{-2} cm/sec (hydraulic transmissivity no less than 3×10^{-5} m^2/sec) at the time of installation.

- Granular material should be no coarser than 3/8 inch (0.95 cm), and classified as SP; it should be smooth and rounded and should contain no debris that could damage the underlying flexible membrane liner (FML), nor should it contain fines that might lessen permeability.

- A filter layer (granular or geosynthetic) should be included between the drainage layer and top layer if necessary to prevent clogging of the drainage layer by fine particles.

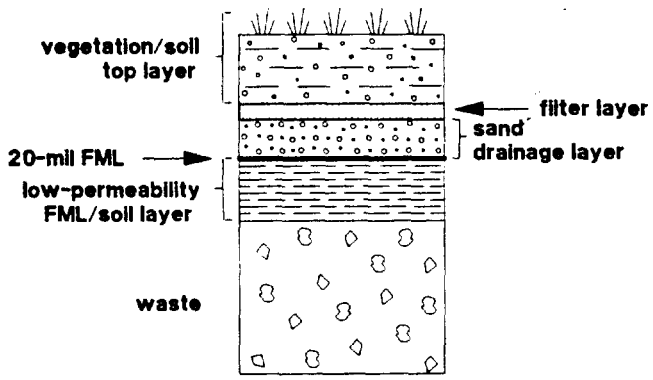

Figure 3a. Cover with sand drainage layer.

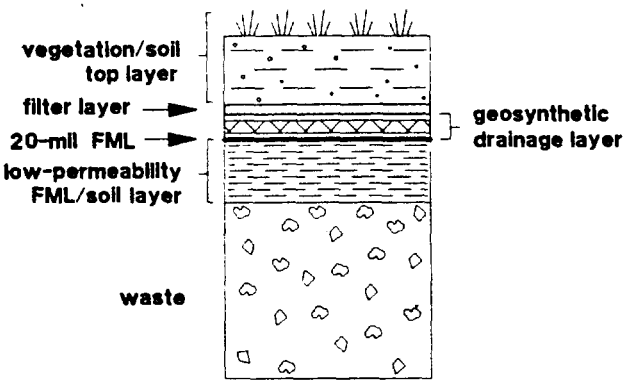

Figure 3b. Cover with geosynthetic drain layer.

If composed of geosynthetic materials (Figure 3b), the Agency recommends that the drainage layer meet the following specifications:

- Same minimum flow capabilility as a granular drainage layer in the same situation; hydraulic transmissivity no less than 3 x 10^{-5} m^2/sec under anticipated overburden for the design life.

- Inclusion of a geosynthetic filter layer above the drainage material to prevent intrusion and clogging by the overlying top layer soil material.

- Inclusion of geosynthetic bedding beneath the drainage layer, if necessary, to increase friction and minimize slippage between the drainage layer and the underlying FML, and to prevent intrusion, by deformation, of the FML into the net or grid of the drainage layer.

The owner or operator should prepare a written construction quality assurance (CQA) plan to be used during construction and installation of the drainage layer (see EPA, 1987b).

3.2 DISCUSSION

The primary functions of the drainage layer are to intercept water that percolates through the top layer and to transport the water out of the cover (for example, by gravity flow to an outlet at the toe of the cover). The Agency believes that the criteria presented above are the minimums required to provide cover drainage and FML protection. The criteria for permeability and FML bedding are equivalent to those cited in "Minimum Technology Guidance on Double Liner Systems for Landfills and Surface Impoundments -- Design, Construction and Operation" (EPA, 1987i) for the leachate detection, collection, and removal system.

The recommended 30-cm (12-in.) minimum thickness of the drainage layer allows sufficient cross-sectional area for transport of drainage in most situations and for protection of the FML during construction. In some cases, particularly where unusually long drainage slopes may be part of the design, drainage layers thicker than 30 cm (12 in.) and/or slopes greater than 3 percent may be necessary. The minimum value of 1×10^{-2} cm/sec for permeability was chosen because granular materials widely used as drainage media (i.e., SP soils) can provide this minimum hydraulic conductivity. In situations where the minimum criteria are insufficient or questionable, the design should utilize flow modelling in arriving at the flow-controlling design parameters. The HELP model (EPA, 1984a) can be of assistance for this purpose.

Rounded grains with a maximum size of 3/8 inch (0.95 cm) have been recommended, because they have been shown to be non-damaging to most FMLs when in direct contact with them (EPA, 1984b). Crushed stone would not normally be appropriate due to sharpness of the particles.

The drainage layer must slope to an exit drain which allows percolated water to be efficiently removed. An example of an exit drain is shown in Figure 4. Further information is provided in EPA (1985a) and Bureau of Reclamation (1977) publications. Care should be taken in the design to control the velocity of the exiting water, within and beyond the exit drains, to prevent soil loss and destabilization. Large safety factors may be needed to accommodate unexpected events.

Materials used to construct the drainage layer should be washed or screened prior to construction to remove fines that may promote clogging. To further prevent clogging of the drainage

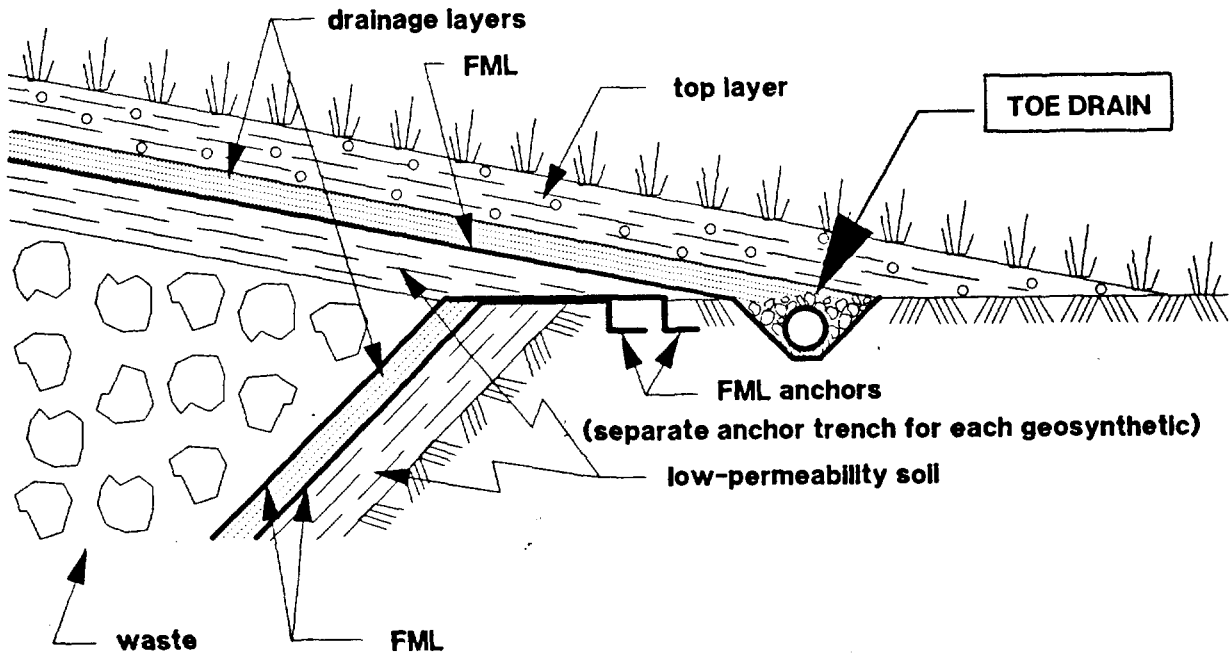

Figure 4. Cover and liner edge configuration with example toe drain.

layer, the Agency recommends that a granular or geosynthetic filter be placed directly over the drainage layer to minimize the migration of fines from the overlying topsoil into the drainage layer. If a graded granular filter is used, care should be taken to design the relationship of grain sizes according to the criteria presented below (Cedergren, 1967).

To prevent piping:

$$\frac{D_{15}\ \text{Filter}}{D_{85}\ \text{Top soil layer}} < 4\text{-}5, \text{ and}$$

$$\frac{D_{15}\ \text{Drainage layer}}{D_{85}\ \text{Filter}} < 4\text{-}5$$

To maintain permeability:

$$\frac{D_{15}\ \text{Filter}}{D_{15}\ \text{Top soil layer}} > 4\text{-}5, \text{ and}$$

$$\frac{D_{15}\ \text{Drainage layer}}{D_{15}\ \text{Filter}} > 4\text{-}5$$

To achieve uniformity of grain size distribution curves among top soil layer, filter, and drainage layer:

$$\frac{D_{50}\ \text{Filter}}{D_{50}\ \text{Top soil layer}} < 25, \text{ and}$$

$$\frac{D_{50}\ \text{Drainage layer}}{D_{50}\ \text{Filter}} < 25$$

These criteria are cited by the Army Corps of Engineers for selection of a filter layer in relation to a soil to prevent the soil from piping through the filter. D_{85} refers to the size of particle in the gradation, below which 85 percent by weight of the particles have a smaller particle size. D_{15} and D_{50} have similar definitions. The criteria must be satisfied for all layers or media in the drainage system, including protected soil, filter media, and drainage media. Criteria for granular and geotextile filter design are found in numerous references (Horz, 1984; Bureau of Reclamation, 1984 and 1977; EPA, 1987e; and Koerner, 1989).

Innovative drainage systems, such as those using geosynthetic materials (see Figure 3b), may be used if it can be shown that they are at least equivalent to the recommended granular system in hydraulic transmissivity, in performance longevity (transmissivity must be maintained for cover's design life), and in their ancillary function as FML bedding. Criteria which should be addressed in determining equivalence of geosynthetic and soil drainage materials include, but are not limited to, the following:

- hydraulic transmissivity (the rate at which liquid can be removed) no less than 3×10^{-5} m^2/sec;
- compressibility (the ability to maintain open pore space and thus transmissivity, under expected overburden);
- deformation characteristics (the ability to conform to changes in the shape of the surrounding materials);
- mechanical compatibility with the FML (the tendency for the drainage material and the FML to deform each other);
- useful life of the system; and
- ability to resist physical, chemical and biological clogging.

Geosynthetic drainage materials are manufactured in a variety of configurations, which continue to evolve with experience in manufacturing and use. "Geonets" and "geogrids" are drainage components designed for rapid flowthrough. They are manufactured as single components that usually must be separated from overlying and underlying soils that could clog them. The separating materials are also geosynthetics in the form of filter fabric. The geogrid, and top and bottom filters (which may also serve as protective bedding and slide-resistant materials), may all be factory-bonded together in one unit. These bonded-together materials, one form of "geocomposites," may be applied in one operation as the entire drainage layer. The various forms of geocomposites are well-described by Koerner (1989). In geosynthetic materials are continually being improved by the manufacturers for durability and design.

4. LOW-PERMEABILITY LAYER

The final cover system is required by 40 CFR 264.228, 264.310, and 265.310 to provide long-term minimization of migration of liquids through the closed land disposal unit and to have a permeability less than or equal to the permeability of the bottom liner system or natural subsoils present. The Agency has interpreted this to mean that the cover should contain a FML/soil composite layer (Figure 5) similar in concept (but not necessarily identical construction materials) to the composite bottom liner detailed in "Minimum Technology Guidance on Double Liner Systems for Landfills and Surface Impoundments -- Design, Construction and Operation" (EPA, 1987i) and in proposed regulations (EPA, 1987a). The two components (FML and soil) of the low-permeability layer recommended in this document are considered to function as one system. They should be designed, constructed, and operated to maximize removal of water by the

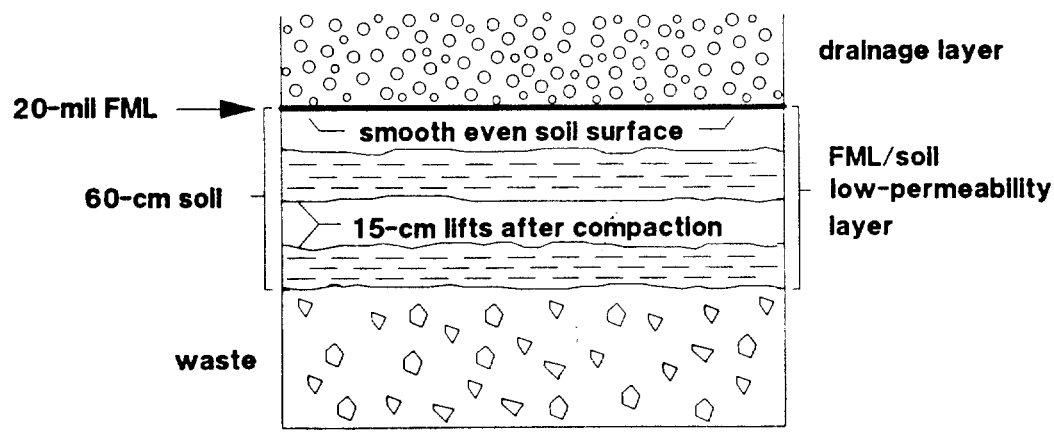

Figure 5. Detail of FML/soil composite low-permeability layer.

overlying drainage layer and to minimize infiltration of water into the waste. The low-permeability layer should require little or no maintenance during and after the post-closure period. The Agency recommends the same design for both permitted and interim status units, although it may not be required for some interim status units.

4.1 DESIGN

The Agency recommends that the low-permeability layer be located below the maximum depth of frost penetration and, at a minimum, consist of the following two components:

1. An upper FML component with the following characteristics:

   a. The FML should be at least 20 mils (0.5 mm) in thickness, but some units and/or some FML materials may require a greater thickness to prevent failure under potential stress of the post-closure care period, or during construction. The Agency recognizes that some types of FMLs must be thicker to accommodate unique seamability requirements, or to increase long-term durability (e.g., increase resistance to puncture).

   b. The surface of the FML should have a minimum 3 percent slope after allowance for settlement.

   c. There should be no surface unevenness, local depressions, or small mounding that create depressions capable of containing or otherwise impeding the rapid flow and drainage of infiltrating water.

   d. The Agency recommends the use of material and seam specifications such as those in "Lining of Waste Containment and other Impoundment Facilities" (EPA, 1987h).

   e. The FML should be protected by an overlying drainage layer of at least 30 cm (12 in.) of soil material no coarser than 3/8-in. (0.95-mm) particle size, Unified Soil Classification System (USCS) SP sand, free of rock, fractured stone, debris, cobbles, rubbish, roots, and sudden changes in grade (slope) that may impair the FML. The overlying drainage layer should suffice as bedding in most cases, but care should be taken that any included drainage pipes are not placed in a way that will damage the FML.

   f. The FML should be in direct contact with the underlying compacted soil component and should be installed on a smoothed soil surface.

g. The number of penetrations of the FML by designed structures (e.g., gas vents) should be minimized. Where penetrations are necessary, the FML should be sealed securely around the structure.

h. Bridging or similar stressed conditions in the FML should be avoided by providing slack allowances for temperature-induced shrinkage of the FML during installation and during the period prior to placement of the protective layer or drainage layer.

i. Slack should not be excessive to the extent that folds are created that later may crack.

2. A bottom low-permeability soil component with the following characteristics:

a. The soil should be at least 60 cm (24 in.) of compacted, low-permeability soil with an in-place saturated hydraulic conductivity of 1×10^{-7} cm/sec or less.

b. The compacted soil must be free of clods, rock, fractured stone, debris, cobbles, rubbish, and roots, etc., that would increase the hydraulic conductivity or serve to promote preferential water flow paths.

c. The upper surface of the compacted soil (which is in contact with the FML) should have a minimum slope of 3 percent after allowance for settlement.

d. The soil layer should be constructed so that it will be entirely below the maximum depth of frost penetration upon completion of the cover system.

The written CQA plan prepared by the owner/operator should include a separate section specific to monitoring the installation of both the FML and compacted soil liner (see EPA, 1987i).

4.2 DISCUSSION

The Agency believes that the recommended two-component low-permeability layer design (Figure 5) is the best practicable, in most cases, to minimize infiltration of surface water into the underlying waste. Both the FML and the compacted soil components have excellent characteristics to prevent infiltration into underlying waste over the long term when properly designed, installed, and operated in accordance with site-specific conditions. Their characteristics tend to complement each other,

so that the long-term effectiveness of the two components together is greater than each alone. A summary discussion of the comparative effectiveness of the composite liner in the bottom liner application appears in a Federal Register notice (EPA, 1987f). A more complete discussion appears in "Background Document on Bottom Liner Performance in Double-Lined Landfills and Surface Impoundments" (EPA, 1987g). In short, the FML will tend to roof over the inconsistencies in the underlying compacted soil, while the compacted soil will tend to significantly impede the flow of any leakage through a hole in the overlying FML. In addition, each component tends to back up the other in the event of a failure of either.

In the past, due to lack of data on durability, the Agency has considered the FML to be short-lived compared to compacted soil. Thus, the Agency has thought of the FML as fulfilling a function of "short-term prevention" of infiltration, while the soil provides for "long-term minimization." With increasing knowledge of FML characteristics and performance, and the increasing technical ability to custom-tailor FML materials to the containment need, it is now the consensus that they, too, can be made to last for very long periods of time (EPA, 1988a). Of course, this implies that care be taken in the construction, and later operation of the facility, that all design requirements are met, that certain waste consolidation conditions are met to minimize settlement problems, and that physical damage does not occur. The same implication applies to the soil component even though the design requirements and potential physical damage are significantly different.

The following subsections provide more detail on the design rationale for each of the two components of the low-permeability layer.

4.2.1 FML Component

The Agency recommends that, in no case, should the thickness of the FML be less than 20 mils (0.5 mm). The Agency believes that this is the minimum acceptable thickness to meet cover objectives and still be sufficiently rugged to withstand expected stresses during construction and operation. In many, if not most, cases the thickness should be greater. The adequacy of the selected thickness should be demonstrated by an evaluation considering the type, strength, and durability of the proposed FML material, its seamability, and site-specific factors such as: steepness of slopes, physical compatibility with the material used in the underlying and overlying layers, stresses of installation, expected overburden, climatic conditions, settlement, and subsidence.

FML failure mechanisms are discussed in several reports (EPA 1985a, 1983b, 1987h). Most failures result from inadequacies in the design and construction processes. It follows then that most failures can be prevented if a strict quality assurance program is adhered to during the construction process. The Agency has placed great emphasis on construction quality assurance, particularly in the construction of barrier layers, and has published guidance in that area for landfill waste containment liners (EPA, 1986).

One of the causes of FML failure in landfill and surface impoundment lining systems is chemical incompatibility. However, the FML in a final cover should not come in direct contact with any wastes and chemical incompatibility should not be of concern. This makes it possible to accept a wider range of FML materials in cover systems. It should be remembered here that it was not the Agency's intent in the regulations that the bottom liner and cover barrier necessarily be constructed of the same material.

Another of the primary causes of FML failure is damage during installation or operation. To aid in preventing damage, such as punctures, rips and tears, at least 30 cm (12 in.) of bedding material above and below the membrane is recommended. Since the FML is in direct contact with the low-permeability soil layer, that layer will serve as the underlying FML bedding. In most cases, the drainage layer above the membrane will suffice as the overlying FML bedding. A minimum underlying bedding thickness of 30 cm (12 in.) is recommended, the same as for the drainage layer. The actual bedding thickness should, however, be based upon consideration of failure mechanisms and construction methods potentially harmful to the FML (e.g., if construction equipment or methods are capable of penetrating the 30-cm [12-in.] drainage layer and tearing, ripping or puncturing the FML, then the thickness should be increased). If the design thicknesses for drainage and bedding differ, then the greater thickness should be used. Geosynthetic drainage materials may also serve as protective bedding if they can provide equivalent protection for the design life of the cover system.

Penetration of the FML by gas vents or drainage pipes should be minimized. Where a vent is necessary, it is essential to obtain a secure, liquid-tight seal between the structure and the FML to prevent leakage of water around the vent (see Section 5). Settlement of the material around the structure may create destructive stresses in the FML, which should be taken into account in the design of both the structure and the FML collar.

Differential settlement across the cover may also cause disruptive stresses that should be accounted for in the FML design. Care should be taken to make allowance for these and other stresses. For example, wrinkles and folds might be created

intentionally to reduce stress, but they may, in turn, result in stresses in the folds that can lead to long-term failure of the FML (EPA, 1988b).

The subgrade for the FML must be carefully prepared and smoothed so that no small-scale stress points are created due to protrusions of rocks or other materials. In most cases, this should cause no difficulty, since the subgrade will be the low-permeability soil component, comprised of fine material.

Field-seaming of the FML must be done carefully by technicians qualified and experienced in seaming the particular FML being installed. Holes can result from discontinuous seams or those not sufficiently sturdy to withstand unavoidable stresses. Some FMLs require destructive surface preparation (e.g., grinding) prior to seaming; all will expand and shrink with temperature changes. These characteristics may promote later leakage if not carefully considered in the construction process. All of the potential failure causes can be minimized or prevented by using expert installers and adhering to a strict construction quality assurance program (EPA, 1986).

4.2.2. Low-Permeability Compacted Soil Component

The Agency believes that a compacted soil component beneath, and in direct contact with, the FML will:

- minimize, over the long term, liquid migration into the waste in the event of FML failure or through imperfections (holes, tears, etc.) inadvertently left during the construction process;
- provide a firm foundation for the overlying layers of the cover system;
- serve as bedding material for protection of the overlying FML; and
- in conjunction with the FML, satisfy the regulatory requirement for the cover to be no more permeable than the bottom liner of the facility.

The design of the soil layer will depend on site-specific factors including the properties and engineering characteristics of the soil being compacted, the degree of compaction attainable, the total expected load, and the expected precipitation.

The Agency recommends a minimum thickness of 60 cm (24 in.) for the low-permeability soil component. The minimum thickness is based upon constructability considerations and the ability to provide uniformity in overall permeability. Sixty centimeters allows for the installation of four lifts (see Figure 5),

considered sufficient to overcome any inconsistencies in the underlying surface. The four lifts also allow the localized inconsistencies in permeability in one lift to be "sealed" by the overlying lift.

As in the case of landfill liners, the Agency recommends the use of a test fill (EPA, 1986, 1987i, and 1988c) prior to actual construction of the soil component. The purpose is to demonstrate, where appropriate soil is available, that the compacted soil component actually can be constructed to an hydraulic conductivity no greater than 1×10^{-7} cm/sec. (Most of the ensuing discussion assumes that soil will be available that can meet the 1×10^{-7} criterion.) The Agency believes that construction of a test fill utilizing the soil, equipment, and procedures to be used in construction of the low-permeability layer will ensure that design specifications are attainable with the available materials and equipment.

The test fill need not be constructed on the waste. The Agency believes that, if the waste consolidation or compressive strength of the waste is insufficient to allow adequate compaction of the low-permeability soil component, that problem should be corrected before installation of the compacted soil. One of the possible solutions is to install an interim cover, as noted earlier for the mitigation of subsidence. If components of the interim cover can meet the CQA requirements for the final cover, the interim cover could be made an integral part of the final design.

Potential failure mechanisms that must be considered in evaluating the design of the compacted soil component include subsidence, dessication cracking, and freeze-thaw cycling. Subsidence has been discussed in the Introduction. The main factor of concern in design to counter subsidence is the consolidation potential remaining at the time of cover installation. That potential is difficult to estimate, but, in the estimation, information regarding the presence of voids and compressible materials in the underlying waste is all-important. Ordinarily, most of the consolidation that will take place in hazardous waste landfills has occurred by the time of cessation of waste placement (EPA, 1985c and 1987d). An important benefit is the ability of the compacted soil component to deform somewhat without rupturing, a desirable characteristic related to the soil's compressive and tensile strengths under expected field conditions of moisture, density, etc.

The potential for desiccation of the compacted clay component will depend on the physical properties of the clay, design moisture content, local climatology, and moisture content of the underlying waste. The actual clay-size particle content of the soil, the type of clay, and properties such as liquid

limit, plasticity, and shrinkage should be used to select a soil with low cracking potential or in determining placement procedures to reduce cracking potential (RTI, 1983; EPA, 1979).

Compaction of the soil component wet of optimum is recommended by the Agency to assure that the lowest permeability may be attained with standard Proctor densities (RTI, 1983). To guard against drying in this case, the applicant may propose immediate installation of the FML above the soil. If this is done, it must first be assured that the installation of the soil is complete, including a smooth surface on which to directly apply the FML.

Freeze-thaw conditions are an important potential source of damage to the soil component of the low-permeability layer. Cycles of freezing and thawing may cause material cracking, lessening of density, and loss of strength. This is brought about by volume expansion of liquids in pore spaces during freezing which, after thawing, increases the accessibility of liquids to the pore spaces (EPA, 1983b). Cracking may be created due to the expansion associated with freezing. For these reasons, the Agency recommends that, upon completion of cover system construction, the low-permeability layer be entirely below the maximum depth of frost penetration estimated for the area in which the facility is constructed. In other words, the top layer and drainage layer of the cover together should be thicker than the maximum depth of frost penetration. In northern areas of the United States this recommendation would necessitate a top layer thicker than the recommended 60-cm (24-in.) minimum.

Figure 6 is provided to show the variability of mean frost penetration across the United States (Stewart, et. al., 1975). The figure is provided only for perspective. It should not be used to find the maximum depth of frost penetration at any particular site. In determining the site-specific maximum depth of frost penetration, advice may be sought from the Soil Conservation Service, utility companies, construction contractors, and universities in the area of concern.

Penetration of the low-permeability soil component by gas vents or drainage pipes should be minimized. Adequate attention must be given to the design of seals for such penetrations and possible complications induced by differential settlement of natural and man-made materials at penetration points. The Agency has no information specific to the adequacy of seals in the soil component of the low-permeability layer.

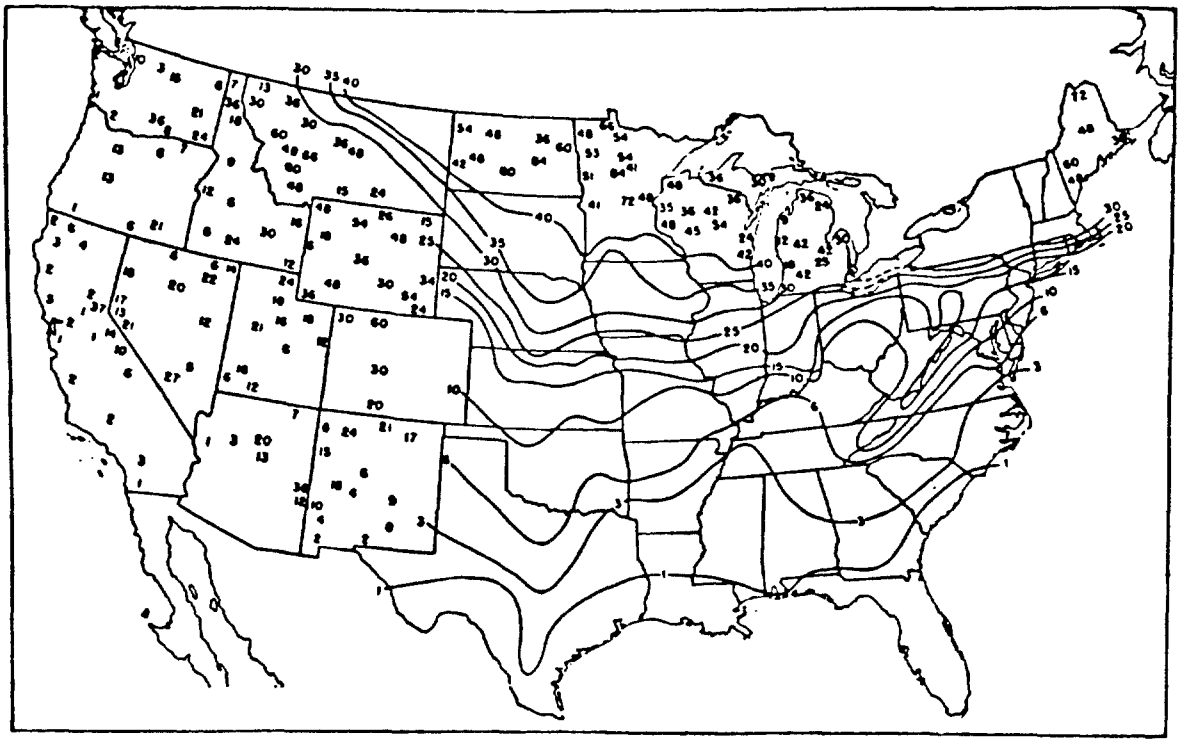

Figure 6. Regional average depth of frost penetration in inches (Stewart, et al., 1975).

5. OPTIONAL LAYERS

The optional layers discussed in this section are the gas vent and biotic barrier layers. Other layers may be needed on a site-specific basis. The Agency does not have information on the performance of these layers in full-scale multilayer cover systems.

5.1 GAS VENT LAYER

The function of a gas vent layer (Figure 7) is to control combustible or toxic gases released from wastes buried in a disposal facility. Hazardous waste disposal facilities that are most likely to require a gas vent layer are co-disposal facilities that receive organic waste material such as that found in municipal waste. However, certain chemicals may also emit gases or vapors in sufficient quantity to require venting.

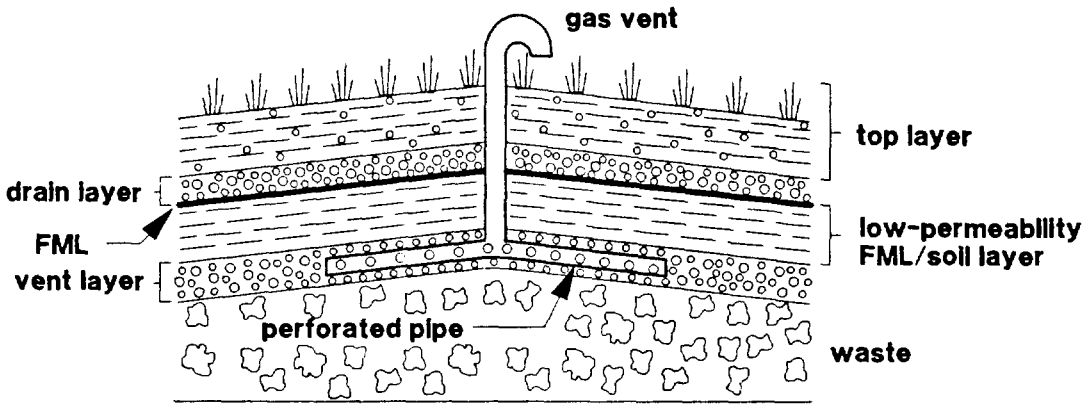

Figure 7. Cover with gas vent outlet and vent layer.

5.1.1 Design

The Agency offers the following design recommendations, based upon engineering judgment, for a gas vent layer:

- The layer should be a minimum of 30 cm (12 in.) thick and should be located between the low-permeability soil liner and the waste layer (see Figure 2).

- Materials used in construction of the gas vent layer should be coarse-grained, porous materials such as those used in the drainage layer.

- Geosynthetic materials may be substituted for granular materials in the vent layer if equivalent performance can be shown.

- Venting to an exterior collection point for disposal or treatment should be provided by means such as horizontal perforated pipes, patterned laterally throughout the gas vent layer, which channel gases to vertical risers.

- The number of vertical risers through the cover should be minimized and located at high points in the cross-section, and designed to prevent water infiltration through and around them.

An alternative design, particularly useful for layered landfills where vertical migration is impeded, may include perforated vertical collector pipes penetrating to the bottom of the landfill. In this case, several cover penetrations may be required, one for each standpipe. Here again, the pipes should be securely sealed to the low-permeability layer. The standpipes may be 30 cm (12 in.) or more in diameter and may be dual purpose, serving also to provide access for measurement of leachate levels.

The written CQA plan prepared by the owner/operator should contain a specific section which covers monitoring the construction and installation of the gas vent system.

5.1.2 Discussion

Materials used in construction of the gas vent layer should have specifications similar to the granular material used for the drainage layer. The materials should be chosen and placed in a way that facilitates the emplacement and compaction of the overlying low-permeability soil component. Once placed, the granular material should allow free movement of gases to collection pipes and/or outlet points.

The outlets may consist of pipes or vents allowing the gas to be collected, vented, or treated. The vent layer and outlet should be designed to minimize cover penetrations which could allow possible liquid infiltration through the cover. Outlet vents should be constructed through the barrier layer at the highest elevation of the gas vent layer to allow maximum evacuation of gas (see Figure 7).

A minimum thickness of 30 cm (12 in.) is recommended to assure that a continuous layer of reasonable thickness (to allow free movement of gases) is provided after placement on a non-uniform waste surface.

In addition to providing gas removal, the gas vent layer may provide a protective foundation upon which to construct the compacted soil liner. The vent layer must be placed over the waste up to design elevation, allowing for estimated settlement, prior to placement and compaction of the soil liner. A filter, either granular or geotextile, may be required between the gas vent layer and the low-permeability soil to prevent clogging.

Alternative gas layer designs (e.g., using geosynthetic materials) may be considered if it can be shown that they provide a level of performance equivalent to a 30-cm (12-in.) granular layer. Equivalence is based upon the ability of the design to efficiently remove any gases produced, resist clogging, prevent infiltration, withstand expected overburden pressures, and function under the stresses of construction and operation.

Designs for gas vent layers can be found in several EPA publications (EPA 1979, EPA 1985a).

Alternative, vertical standpipe gas collectors are constructed of perforated sections, being built up as the unit is filled with waste. They may be constructed of concrete and wrapped with geosynthetic filter material to prevent clogging of the perforations.

5.2 BIOTIC BARRIER LAYER

Plant roots or burrowing animals (collectively described as biointruders) may disrupt the integrity of the drainage and low-permeability layers. The drainage layer may be especially susceptible to the intrusion of plant roots, which could interfere with the drainage capability of the material. The danger of FML penetration by plant intrusion has not been proven. Burrowing animals may be a greater threat to FMLs, if a threat indeed exists. In the absence of an FML, the low-permeability soil layer could be exposed to both root and animal penetration.

Physical barriers, such as layers of cobbles or coarse gravel beneath the top layer, and chemical barriers, have been proposed to discourage or reduce the threat of biointrusion.

5.2.1 Design

The Agency knows of no full-scale application that would prove the effectiveness of a biotic barrier in a landfill situation. Therefore, the design of such a barrier must rely on the results of small-scale field experiments. Experiments with

barrier layers of cobbles have been carried out in arid or semi-arid situations, with plants unique to such habitats (Cline, 1979 and Cline, et al, 1982). Some research suggests that three feet (90 cm) of cobbles, or six inches (15 cm) of gravel over 30 inches (75 cm) of cobbles, may be effective in stopping root penetration of some deep-rooted plants (DePoorter, 1982). It may also be effective in stopping the invasion of burrowing animals. The biotic barrier layer would directly underlie the soil component of the top layer, perhaps separated by a geosynthetic filter layer.

A polymeric herbicide carrier/delivery (PCD) system, used to release herbicide, as discussed by Cline, et al. (1981), might be installed within a cover, also just above the drainage layer to stop the intrusion of roots below the system. The PCD system would contain an herbicide designed to be released slowly over many years. Note here the probable reluctance of the Agency in approving this alternative, because it may introduce a hazardous waste to the cover system, and/or it may not last through the 30-year post-closure period.

5.2.2 Discussion

Research by Cline (1979) and Hokanson (1986) found that if objects, such as cobbles, placed in a burrowing animal's path are too large or tightly packed, the animal's progress is effectively stopped. Hokanson also found that large void spaces, which lack water and nutrients, within the layer of stone, reduced the intrusion of plant roots. On the other hand, the layer of very coarse materials, at least in arid areas, may favor the growth of grasses by impeding the downward percolation of moisture, thus helping to retain it in the top soil layer.

Cline et al. (1982) also looked at the effectiveness of several phytotoxins impregnated into polymeric sheets and buried in soil. Some of them met the goal of being effective in stopping the downward progress of root growth, with no other effects. Some of the phytotoxins killed the plants when the roots encountered the sheet, while others had no effect. Obviously, a chemical biotic barrier must be chosen carefully, if at all, to avoid potentially adverse environmental effects.

Most of the research on the effectiveness of biotic barriers has been done in arid areas. Thus, the results must be used with caution in areas of greater precipitation. The design and resulting effectiveness of a biotic barrier are site-specific and dependent upon the overlying topsoil layer, biotic barrier material, natural precipitation, and anticipated biointruders.

1. INTRODUCTION

The passage of the 1987 amendments to the Clean Water Act brought about significant changes in the regulation of the use and disposal of municipal sewage sludge. Although the Clean Water Act had required since 1977 that EPA develop technical standards for sludge use and disposal, the 1987 amendments required that these standards, when promulgated, be implemented through permits. The amendments also state that prior to promulgation of the technical standards, EPA must include sludge conditions in NPDES permits issued to publicly-owned treatment works or take other appropriate measures to protect public health and the environment from pollutants in sewage sludge. This requirement has initiated a program for "case-by-case" permitting to ensure protection of the environment prior to the issuance of final sludge standards which are scheduled for promulgation in October 1991.

This focus on sludge permitting places increased emphasis on the need to assess sewage sludge quality. In policy and guidance documents that EPA has developed for implementing the sludge requirements of the Clean Water Act, the Agency has recommended that POTWs sample and analyze their sludge at least annually to determine if the sludge quality is such that the sludge may be safely reused and recycled or disposed. Accurate characterization of sludge composition spots operational problems at the treatment works and may also signal adverse environmental impacts. In addition, sludge sample and analysis is needed to assess compliance with current requirements (e.g., 40 CFR Part 257 requirements for cadmium and PCBs).

In view of the variability of municipal sludge quality, appropriate procedures must be followed to collect and analyze samples that accurately represent each POTW's sludge quality. This manual was developed to provide that guidance to POTW operators, engineers, managers, chemists and permit writers. It was intended to provide guidance in developing and implementing a sampling and analysis program, to gather information on sludge quality and determine compliance with permit conditions. This manual is based on current, state-of-the-art field and laboratory practices and therefore is recommended for all sludge sampling and analysis programs.

2. SLUDGE SAMPLING

2.1 BACKGROUND INFORMATION

Depending on the use or disposal practice, it may be necessary to sample various sludge types throughout a given POTW. In order to sample a sludge stream effectively, it is necessary for sampling personnel to be aware of the physical characteristics of the sludge stream(s) at intended sampling locations.

2.1.1 Solids Content and Viscosity

Two important physical characteristics of sludge with respect to sampling and analysis are viscosity and solids content. Solids content is the percent, by weight, of solid material in a given volume of sludge. Sludges have a much higher solids content than most wastewaters. Solids content and solids settling characteristics determine whether a given sludge will separate into different fractions which increases the potential of obtaining a nonrepresentative sample.

Viscosity is the degree to which a fluid resists flow under an applied force. The viscosity of a sludge is only somewhat proportional to solids content. This property affects the ability to automatically sample a liquid, since friction through pipes is proportional to liquid viscosity. In general, sludges of up to 20 percent solids may be conveyed by means of a pump. Sludge with a greater solids content, often referred to as sludge cake, must be conveyed by mechanical means. Automatic samplers that rely on pumps may be useful only for liquid sludges with a solids content of less than 20 percent. However, sludge cakes require manual grab sampling. Other problems created by sludge

solids (see Section 2.3.1) generally preclude the use of automatic samplers.

Solids content is also significant from an analytical standpoint. Increased solids content may require sample dilution and cause a corresponding increase in experimental error and detection limits. Also, water removal through dewatering can either concentrate parameters of interest in the sludge and increase analytical accuracy, or carry away pollutants and decrease pollutant concentration and analytical accuracy. Analytical precision (repeatability) and accuracy (closeness to true value) may also decrease as the concentration of interfering compounds and matrix effects increase, due to higher solids content after dewatering.

2.1.2 Processed Sludge Characteristics

The quantity and quality of sludge generated depends on raw wastewater characteristics and the sludge treatment practices. The sludge to be sampled may be in the form of a liquid, dewatered cake, compost product, or dried powder. Some of the physical characteristics of each sludge type are described below.

2.1.2.1 Anaerobically Digested Sludge

Anaerobically digested sludge is a thick slurry of dark-colored particles and entrained gases. When well digested, it dewaters easily and has a non-offensive odor. The addition of chemicals coagulates a digested sludge prior to mechanical dewatering. The dry residue of digested sludge contains 30 to 60 percent volatile solids. Depending on the mode of digester operation, the percent solids of digested sludges ranges from 4 to 8 percent.

2.1.2.2 Aerobically Digested Sludge

Aerobically digested sludge is a dark-brown, flocculent, relatively inert waste produced by long-term aeration of sludge. The suspension is bulky and generally difficult to thicken. The odor of aerobically digested sludge is not offensive. The percent solids of aerobically digested sludge is less than that of the influent sludge (if not decanted), because approximately 50 percent of the volatile solids are converted to gaseous end products during aerobic digestion.

2.1.2.3 Dewatered Sludges

Dewatering converts sludge from a flowing mixture of liquids and solids to a cake-like substance more readily handled as a solid. The characteristics of dewatered sludge depend on the type of sludge, chemical conditioning, and treatment processes employed. The percent solids content of dewatered cake ranges from 15 to >40 percent. Cake with a lower percent solids is similar to a wet manure, while cake with a higher percent solids is a chunky solid.

2.1.2.4 Compost Product

Composting is a process in which organic material undergoes biological degradation to a stable end product. Properly composted sludge is a sanitary, nuisance-free, humus-like material containing 75 to 80 percent solids. Approximately 20 to 30 percent of the volatile solids are converted to carbon dioxide and water.

2.1.2.5 Dried Powder

Dried powder is the residue from heat drying processes. Sludge drying reduces water content by vaporization of water to permit sludge grinding, weight reduction, and to prevent

continued biological action. The moisture content of dried sludge is less than 10 percent.

Incinerator ash is a product of the incineration of sewage sludge. Ash is therefore not covered under the sampling or analysis of sewage sludge. It is covered under RCRA Subtitle C if it is a hazardous waste and if not it falls under Subtitle D.

2.2 SAMPLE POINT SELECTION

2.2.1 General Considerations

NPDES, pretreatment and sludge program officials need sludge quality data in order to determine whether sludge use or disposal may pose a threat to public health or the environment. Thus, as a general rule, sludge samples should be drawn from an appropriate sampling point and in such a manner that the sample represents, as well as possible, the quality of the sludge as it will be disposed of or used. When selecting a specific sample point, the following two factors should be carefully considered:

- Does the sample point represent the entire sludge stream?
- Are the sludge stream flow or mass flux data available?

The following paragraphs examine both factors and present recommendations on means to address each factor.

2.2.1.1 Sample Point Representation of the Entire Sludge Stream

Often it is not possible to obtain a wholly representative sample of a given wastestream at any one time. Effort must be made, however, to ensure that a sample is obtained that is as representative as possible. Three concerns that need to be

addressed to ensure that the sample points selected will provide representative samples of the entire sludge stream are: obtaining samples that are representative of the cross-section of the entire flow; obtaining well mixed samples; and obtaining samples of multiple sludge streams.

A particular concern in any sampling program is to obtain samples which represent the entire flow past the sample point throughout the sample period. Each discrete sample should represent the cross-section of the entire flow at the sampling point. Each composite sample of multiple contributory streams should represent the cross-section of the entire flow of the combined stream.

Samples should be obtained from points where the sludge is well-mixed. While some pollutant parameters are predominantly associated with the solids fraction (particularly precipitated metals), others are more associated with the liquid-fraction (many dissolved organics). Failure to acquire a sample with representative solid/liquid fractions can significantly affect the analytical results of a given sample. This is particularly true of sludge streams with high percent solids and large floc particles. Since turbulence ensures mixed samples, these recommendations should be followed:

- In sludge processing trains, samples from taps on the discharge side of sludge pumps are well mixed since flow at this point in the system is turbulent with no solids separation within the flow stream.
- If a sample is drawn from a tap on a pipe containing sludge which is distant from the sludge pumps, the average flow velocity through the pipe should be greater than 2 feet per second (fps). Average velocities of less than 2 fps result in solids separation and settling, and affect sample solids content, depending on the location of the tap (top,

side or bottom of the pipe). Given a choice, a tap on the side of the pipe is preferable. In addition, the tap should be a large size to encourage draw from the entire cross-section of flow when fully open.

At times it may be necessary to sample a poorly mixed open channel flow. If this cannot be avoided, then each sample must be a composite consisting of grabs taken at several levels (1/4, 1/2 and 3/4 depth, for example) in order to minimize sample bias caused by solids stratification. For sampling solid sludges (i.e. dewatered cake, compost, etc.), stratification can be avoided by not only sampling at various depths, but at numerous locations over the entire sludge pile.

Although it is preferable to sample sludge just prior to its exit from the treatment plant in a combined stream, sometimes that is not possible. Therefore, a consideration in many sludge sampling situations is the need to produce a composite sample from confluent streams. An example is the sampling of sludge flows from several parallel sources which later combine downstream in an unsafe or inaccessible location. Several options exist to accommodate multiple streams. The most appropriate choice depends on the sludge flow and solids flux information available, the parameters being sampled and the purpose of the generated data. Several options are as follows:

- The simplest option is to withdraw equal volumes of sample from each of the multiple sludge streams to create a composite sample. This approach is justified in the case of identical units receiving equal flow and generating equal sludge amounts.
- A second option is to weight the grab samples in each composite according to the wastewater flow to each unit (or in the case of filter cake, the thickened sludge flow to each unit). This approach recognizes that for different sized units with different design flows, the volume of sludge produced will theoretically be

proportional to the influent flow to the unit. However, factors such as unequal loading rates, differences in sludge collection mechanisms, etc. can affect solids removal rates and sludge generation rates by unequal, parallel treatment units. This option particularly applies to situations where no sludge flow or solids data exists for unequal parallel flow streams.

- The third option is to weight grabs from individual streams based on sludge flow data or solids flux data. Whether to use sludge flow or solids flux will depend on the sample streams, the parameters of interest, and the planned use of the resulting data. For example, if filter cake is being monitored for compliance with land application limits, solids flux data would be used as the criteria for proportioning grabs from parallel dewatering systems, since most land application limits are based on dry weight application rates.

2.2.1.2 Availability of Flow Data and/or Solids Flux Data

The availability of accurate solids flux data (weight/time) or accurate flow data (volume/time) is an important consideration in planning a sludge sampling program. Most information requirements relating to sludge characteristics involve, at least in part, the need for data on the solids flux of pollutant parameters found in sludge discharged from a POTW. The percent solids should be determined on sludge samples.

Portable flow monitoring devices are not well suited to high-solids flow streams, and most sludge processing streams are not designed in a manner which is physically conducive to the use of these devices. Thus, in most cases, it is necessary to rely on existing integrated flow monitoring equipment. Due to difficulties in monitoring sludge flows, flow meters are high maintenance items. Frequent calibration of sludge flowmeters is necessary in order to ensure accurate flow measurement. This data should be cross-checked against mass balance data. When ultimate use or disposal practices dictate monitoring sludge with

a high solids content, liquid flow meters are replaced by gross weight scales. Table 2.1 summarizes the types of flow measurement equipment employed to monitor various sludge flows.

2.2.2 Sludge Sample Points

The determination of the appropriate sludge sampling point is dependent on the rationale behind the sampling. For permits and regulation enforcement, sludge samples must come from the treatment unit process immediately preceding disposal or use. For example, if a POTW disposes of its dewatered filter cakes in a sanitary landfill, then sampling activity focuses on the output sludge stream from the dewatering device (i.e., vacuum filter, belt filter, etc.). The sludge treatment processes commonly employed are stabilization, dewatering, drying, composting, and thermal reduction. Table 2.2 summarizes sampling points for these processes. Other sludges sampling points may be necessary to examine the origin or fate of pollutants within a POTW, (i.e., additional sludge samples from influent and output of other processes may be needed).

2.3 SAMPLE COLLECTION

Having selected appropriate sampling points for a sludge sampling program, it is then necessary to determine the method and equipment by which sampling will be carried out. In doing so, the following objectives should be considered:

- Each grab sample, or aliquot of a composite sample, must be as representative as possible of the total stream flow passing the sampling point
- Effort must be made to minimize the possibility of sample contamination
- The selected sampling method should be safe, convenient and efficient.

TABLE 2.1. SLUDGE FLOW MEASUREMENT DEVICES

Application	Measurement Means
Stabilized Sludge	Venturi Flow Tube Magnetic Meter Positive Displacement Pump
Thickener	Magnetic Meter Positive Displacement Pump
Dewatering	Belt press scales
Drying Composting Thermal Reduction	Bulk container or truck scales

TABLE 2.2. SLUDGE SAMPLING POINTS

Sludge Type	Sampling Point
Anaerobically Digested -	Sample from taps on the discharge side of positive displacement pumps.
Aerobically Digested -	Sample from taps on discharge lines from pumps. If batch digestion is used, sample directly from the digester. Two cautions are in order concerning this practice: (1) If aerated during sampling, air entrains in the sample. Volatile organic compounds may purge with escaping air. (2) When aeration is shut off, solids separate rapidly in well digested sludge.
Thickened Sludges -	Sample from taps on the discharge side of positive displacement pumps.

TABLE 2.2. SLUDGE SAMPLING POINTS
(continued)

Sludge Type	Sampling Point
Heat Treatment	Sample from taps on the discharge side of positive displacement pumps <u>after</u> decanting. Be careful when sampling heat treatment sludge because of: (1) High tendency for solids separation (2) High temperature of sample (frequently >60°C as sampled) can cause problems with certain sample containers due to cooling and subsequent contraction of entrained gases.
Dewatered, Dried, Composted, or Thermally Reduced various depths.	Sample from material collection conveyors and bulk containers. Sample from many locations within the sludge mass and at
Dewatered:	
Belt Filter Press, Centrifuge, Vacuum Filter Press	Sample from sludge discharge chute.
Sludge Press (plate and frame)	Sample from the storage bin; select four points within the storage bin, collect equal amount of sample from each point and combine.
Drying Beds	Divide bed into quarters, grab equal amounts of sample from the center of each quarter and combine to form a grab sample of the total bed. Each grab sample should include the entire depth of the sludge (down to the sand).
Compost piles	Sample directly from front-end loader as the sludge is being loaded into trucks to be hauled away.

Except for limitations on the use of automatic sampling devices, the actual sampling techniques for sludges are similar to those found in wastewater sampling. The following sections describe two important considerations for selecting appropriate sludge sampling methods: sampling equipment and proper sampling practices.

2.3.1 Sampling Equipment

In general, automatic sampling devices, which are widely used for wastewater streams, do not work well for sludge streams because of the solids content and viscosity of sludges. Automatic samplers which use pumps to draw samples up a suction tube cause solids separation if flow velocity in the suction and discharge tube is too low. This increases pump head requirements and limits the range of tubing diameter. A second problem which occurs in the use of automatic samplers is fouling of tubing and/or pump structure by sludge solids. This results in contamination of subsequent aliquots during composite sampling. Sludge particles may also plug the sample tube or pumping mechanism and interrupt sample collection. Therefore, it is preferable to sample liquid sludge streams manually, particularly if sample taps can be provided on pump discharge lines.

Sampling equipment must be made of materials which will not contaminate or react with the sludge. The best material choices are Teflon, glass, and stainless steel because they are relatively inert. When the cost of Teflon and stainless steel equipment prohibits or restricts their use, plastic, steel and/or aluminum may be substituted for most sampling activities. (If steel equipment is used, ensure that galvanized or zinc coated items are not used because these materials will readily release zinc into the sample.)

Graduated glass or plastic pitchers or cylinders are used to draw grabs for manually composted samples. Stainless steel pitchers are also commercially available, and are used to grab samples from taps and also can be affixed to lengths of conduit to sample from open channel flows. Only aluminum conduits should be used since most commercially available steel conduit is galvanized. In addition, only stainless steel clamps should be used to attach the sample container to the conduit.

2.3.2 Proper Sampling Practices

Listed below are practices that should be followed when sampling sludges:

- Clean all sampling equipment between each sample period to prevent cross-contamination. Cleaning consists of thorough washing with a laboratory detergent, thorough rinsing with tap water and then with at least three distilled water rinses.
- Sample aliquots should be composted directly into sample containers. Sample containers, preservation of sample and allowable holding time prior to analysis are discussed in Section 2.5.
- When collecting samples for oil and grease analysis, sample directly into the sample container since oil and grease tend to adhere to surfaces. Sample composites should be sent to the laboratory as a series of grab samples.
- Sample collection procedures should be adequately documented, as discussed in Section 2.7.
- When collecting samples for organic volatiles or semi-volatiles, carefully pour liquid sludge into container so as to avoid entrapping air within sample. Fill container to overflowing and screw on lid. Check air bubbles by turning container upside down and tapping lid. If air bubbles rise, open container and fill with additional sample. For sludge cake, care-fully pack sludge into container so as to avoid air spaces. Fill the container to overflowing and screw on lid.

- When collecting samples for dioxin/furan, fill the container to 4/5 full to enable expansion of samples when they are frozen.

- When collecting samples for pesticides/PCBs/herbicides, metals and nonconventionals, fill container to within 1/2 inch of the top to provide room for expansion should there be any gas production during sample shipment.

When sampling liquid sludges:

- To draw a fresh representative sludge sample from a tap:

  a) Allow sufficient time following pump start up to clear line of stagnant sludge, and

  b) Allow sludge to flow for several seconds from tap prior to sampling in order to flush out stagnant sludge and solids accumulated in the tap.

- Before drawing a sludge sample, rinse each piece of sampling equipment 3 times with sample to reduce the chance of contamination from the previous grab.

- To prevent solids separation in the sample, use glass, Teflon-coated stirring rods, or stainless steel spoons to mix the sample before splitting or transferring any portion of it to another container(s).

When sampling solid sludges:

- For either dewatered cakes, dried powder or compost product, combine equal amounts collected at various locations/depths for each grab sample to obtain a more representative sample.

  a) To produce a sample from multiple sample locations (e.g., two or more dewatering units), combine the grab samples from each location (equal amounts or weighted based on flow or solids flux data) in a plastic or stainless steel pail and thoroughly mix the sample (with a scoop or spoon), then transfer it to sample containers. This is not appropriate for volatile or microbial samples.

b) When sampling drying beds, divide each bed into quarters. From the center of each quarter, collect a single core sample through the entire depth of the sludge using a coring device. Usually a small amount of sand will be collected; avoid large amounts of sand. Combine and thoroughly mix in plastic or stainless steel pail and transfer to sample containers.

2.4 SAMPLE SIZE, SAMPLE TYPE, AND SAMPLING FREQUENCY

Sample Size

A proper sample is small enough to transport conveniently and handle carefully in the laboratory, but large enough to accurately represent the characteristics of the whole material. Minimum sample sizes required for accurate analysis are specified in each analytical method. Table 2.3 lists minimum sample sizes for some common analytical methods. For methods not listed here, consult an analytical methods reference or the laboratory for further guidance.

Sample Type

A grab sample collected at a particular time and location can represent the composition of the source only at that time and location. In the case of most sludges, single grab samples will adequately represent only the instantaneous composition of the material being sampled. The quality of a grab sample will be improved if it is comprised of several smaller samples taken over a period of a few minutes.

A composite sample gives a better reflection of the time- and location-weighted average concentrations that are found in the sludge flow stream. In most cases, the term "composite sample" refers to a mixture of grab samples collected at the same sampling point at different times. Although a 24-hour composite

TABLE 2.3

CONTAINERS, PRESERVATION, HOLDING TIMES, AND MINIMUM SAMPLE VOLUMES[1]

Parameter	Wide-mouthed Container	Preservative[2]	Maximum Holding Time[2]	Minimum Sample Volume[3]
Inorganic Compounds

(w/o) Without preservatives

sample (consisting of a number of time- or flow-weighted grab samples) is more representative than a grab sample, it can give a picture of only one day's sludge quality. Historical data is necessary to truly represent the sludge quality. A composite for volatile components analysis is produced in the lab from grab samples collected in the field.

Sampling Frequency

As sludge quality is directly related to wastewater influent quality (which can vary from day to day and hour to hour), a POTW should sample and analyze its sludge frequently to obtain representative data. Collection of representative sludge data is crucial because the permitting authority will use the resultant analytical data to establish permit monitoring parameters and frequencies, and thereafter, to assess compliance with the permit and to ascertain if there is a potential for adverse environmental impacts. POTW operators should be aware that EPA's "Strategy for Interim Implementation in Permits Issued to POTWs" (draft June 1988) to be finalized during the fourth quarter of 1989) sets forth minimum recommended monitoring frequencies to be included in the NPDES permit when it is reissued. The Interim Strategy is scheduled to be finalized in the summer of 1989. The NPDES permit writer may decide based on his/her best professional judgment (BPJ) that more frequent monitoring is needed. The sampling frequency will be set out in the POTW's permit.

To the extent practicable, the POTW should have a sludge sampling program which adequately addresses random and cyclic variation within the system and the potential for human exposure to sludge once it is disposed of or used.

- Anticipated cyclical variation in pollutant loadings - although they are difficult to accurately predict, anticipated cycles include daily industrial production

cycles, weekly industrial production cycles, and other known or suspected production cycles, particularly those associated with intermittent batch discharges by significant industries. Longer-term production cycles, including seasonal and annual/multi-year production cycles (e.g., business cycles), do not need to be considered in determining monitoring frequency unless they are known to affect short-term variation in sludge quality.

- **Risk of environmental exposures** - As the risk of environmental exposure from sludge use/disposal increases, a POTW should increase its sampling frequency to provide better information about potential variation in sludge quality. For example, a sludge that is applied to food-chain croplands should be sampled more frequently than sludge that is disposed of in a landfill that has an impermeable liner and a groundwater monitoring system.

Other factors that should be considered in determining sampling frequency include:

- **Size** - As influent flow increases, day-to-day sludge variability increases, as does outflow volume. Thus, where high volumes exist, the risk of adverse exposure is higher. Since variability and potential impact are major considerations, many sampling programs are based on size alone (e.g. 40 CFR Part 503 proposed rule). Size is also an easy factor to measure.

- **Percentage of industrial flow** - While sludge quality variability is directly related to the individual characteristics of each POTW, POTWs with little or no commercial/industrial contributors in the system can expect relatively small variation in sludge quality. POTWs with significant industrial contributions can expect to have monthly, weekly and even daily variation in sludge quality.

- **Treatment plant characteristics** - As either detention time or mixing increases within a treatment plant, sampling frequency can be reduced since treatment processes will effectively composite sludge to a greater degree. For example, high rate digestion and storage/blending facilities will provide mechanical mixing of sludge. Other plant technologie , such as anaerobic digestion, aerobic digestion and storage,

provide longer sludge detention times, enabling greater mixing through physical processes such as diffusion, convection, etc. For combined sewer systems, a sampling strategy may be designed to monitor the effects of storm events on sludge quality.

Another consideration is the type(s) of information a POTW wishes to collect. If, for example, a POTW desires to measure daily variation over a typical week, the POTW may collect and analyze seven or more 24-hour composite samples for the pollutant. Similarly, if a POTW wishes to measure variation within a single day, the POTW may collect and analyze several grab samples taken at different times during the day.

2.5 SAMPLE PREPARATION AND PRESERVATION

There is the potential for errors of varying severity to be introduced during sample collection and storage which affect analytical determinations. To avoid potential errors and maintain sample integrity, POTW operators should carefully consider the following:

- Sample Container Material
- Sample Container Preparation
- Sample Preservation
- Holding Time Prior to Analysis.

Table 2.3 lists recommended container materials, preservatives, holding times, and minimum sample volumes for the analysis of sludges. For method-specific details concerning all facets of sample preparation and preservation, consult the references cited in 40 CFR Part 136, "Guidelines for Establishing Test Procedures for the Analysis of Pollutants."

2.5.1 Sample Container Material

The requirements for sample containers are method-specific, but containers are usually made of Teflon, glass or polyethylene. Sample containers should be wide-mouthed for sludge sampling, particularly for solids (cake) sampling. Teflon containers are typically supplied with Teflon caps. Glass containers frequently are supplied with caps which can cause sample contamination (phenol, phthalate compounds). For organic parameters, these glass container caps should be fitted with Teflon liners; aluminum liners could be used but they must be fitted precisely within the circumference of the cap to prevent tearing and possible sample leakage.

2.5.2 Sample Container Preparation

Proper sample container preparation is necessary to prevent contamination of the sample by material left from the container manufacturing process or that has otherwise been introduced into the unused sample containers. All containers should be washed with a good quality laboratory detergent, thoroughly rinsed with tap water, and then rinsed at least 3 times with distilled water prior to air drying. Additional container preparations for analysis of particular parameters are described below:

- **Extractable Organics** - Use glass containers with Teflon-lined caps only. Wash containers as above and rinse with solvent (typically methylene chloride); air-dry.
- **Volatile Organics** - Prepare containers by washing and rinsing as described above, and then bake both vials and septums at 105°C until dry. Cool in an organic-free atmosphere.
- **Metals** - Wash and rinse as described above. Then rinse with dilute acid (1 part deionized, distilled water to 1 part nitric acid (HNO_3)), followed by two rinses with deionized, distilled water.

2.5.3 Sample Preservation

Table 2.3 presents U.S. EPA's recommended preservation protocols. These protocols are primarily intended for effluent monitoring; however, they are generally applicable to liquid sludge sampling.

The following are specific recommendations regarding sample preservation:

- In instances where it is desirable to split one composite sample into several fractions, each having incompatible preservation requirements, it is acceptable to chill the entire sample to 4°C during compositing. Following the sample period, the composite is then cautiously mixed and split into various fractions, each of which is appropriately preserved. This does not apply to samples for analysis of volatile, semivolatile or microbial contaminants.

- If processing of microbial samples cannot occur within one hour of collection, iced coolers should be used for storage during transport to the lab. Samples should be held below 10°C during the maximum transport time of 6 hours. Note: these samples must be immediately refrigerated and processed at the lab within 2 hours of receipt.

- Whenever possible, sample containers should be pre-preserved. Thus, grab samples are preserved upon sampling and composite samples are preserved during compositing. This is not appropriate, however, when sampling for metals or pathogens.

- In general, all samples should be chilled (4°C) during compositing and holding.

- For solid sludge samples (cake), adding chemical preservative is generally not useful since the preservative usually does not penetrate the sludge matrix. Preservation consists of chilling to 4°C.

- When sampling and holding sludges, particularly biologically active sludges, gas production in the sealed container may cause an explosion unless the pressure is periodically released. This should not be

done however if volatile or semivolatile pollutants are to be analyzed.

2.5.4 Holding Time Prior to Analysis

Table 2.3 lists the maximum holding times for various pollutant samples. Table 2.4 lists some potential interferences that may affect samples during shipping and storage. There are many more interferences associated with particular analytical methods, which are discussed further in chapter 3 as well as in the particular methodology.

2.6 PACKAGING AND SHIPPING

When analysis will be performed away from the sampling locale, samples must be packaged and transported.

2.6.1 Packaging

Sample containers must be packaged in order to protect them and to reduce the risk of leakage. Containers should be held upright and cushioned from shock. In addition, sufficient insulation and/or artificial refrigerant ("blue ice") should be provided to maintain a sample temperature of 4°C for the duration of transportation.

2.6.2 Transportation Regulations

The following guidelines control the shipment of wastewater and sludge samples:

- Unpreserved normal (i.e., not heavily contaminated) environmental samples are not regulated under DOT Hazardous Material Regulations. These samples may be shipped following the packaging guidelines in Section 2.6.1, and using a commercial carrier, etc. To assure proper sample temperature, transit time should be held to less than 24 hours.

TABLE 2.4

POTENTIAL INTERFERENCES ASSOCIATED WITH
SAMPLE SHIPPING AND STORAGE

Parameter	Interferences[1]	Prevention
Acidity	Carbon dioxide loss	Fill container completely
Ammonia	Chlorine Volatilization	Sodium thiosulfate Fill container completely
Cyanide	Sulfides	Cadmium nitrate, tetrahydrate
Chromium VI	Reducing agents	Minimize holding time
Phenols	Hydrogen sulfide, Sulfur dioxide Oxidizing agents	Aerate Ferrous sulfate
Silica	---	Avoid freezing
Sulfide	Aeration, agitation	Fill container completely
Sulfite	Aeration, agitation	Fill container completely
Organic Chemicals	Photodegradation	Use brown glass container

1 Other than those addressed by protocols shown in Table 2.3

- When environmental samples are preserved as recommended (see Table 2.5), they may be shipped as non-hazardous samples.

The guidelines above assume no material is present in the samples at concentrations which would result in a "hazardous" DOT rating. Should hazardous material (as defined by DOT) be present, DOT regulations concerning packaging, transportation and labeling must be followed (see 49 CFR Parts 172, 173 and 178). A material is considered hazardous by DOT if it fails one of the four characteristic tests of: corrosivity, ignitability, reactivity and EP Toxicity [see "Test Methods for Evaluating Solid Waste, SW 846, 1986 for exact methods]. Municipal sewage sludges labeled as hazardous are usually from failed EP Toxicity tests and occasionally from reactivity tests.

2.7 DOCUMENTATION

Adequate documentation of sludge sampling activities (1) is important for general program quality assurance/quality control, and (2) is required by most monitoring regulations. Proper sampling activity documentation includes proper sample labeling, chain-of-custody procedures and a log book of sampling activities. The number of people in the chain of custody should be kept to a minimum to limit the possibility of contamination and to increase accountability.

2.7.1 Sample Labeling

It is important that each sample label include the following information (items in bold text are minimum elements):

- Sampling Organization Name
- **Facility Name (being sampled)**
- Bottle Number (specific to container

TABLE 2.5

STANDARD PRESERVATIVES LISTED IN THE HAZARDOUS MATERIALS TABLE (49 CFR 172.101) USED BY EPA FOR PRESERVATION OF WATER, EFFLUENT, BIOLOGICAL, SEDIMENT, AND SLUDGE SAMPLES

Sample Type/ Parameter	Preservative	pH Recommendation	Quantity of Preservative Added Per Liter*	WT. % of Preservative
Organic Carbon	Hydrochloric acid	<2 ->1	2 ml of 1:1	0.04%
Nitrogen Species	Mercuric chloride	N.A.	40 mg	0.004%
Metals, Hardness**	Nitric acid	<2 - >1	5 ml of Conc. (70%)	0.35%
Nitrogen Species COD, Oil & Grease, P (hydrolyzable) Organic Carbon	Sulfuric acid	<2 - >1	2 ml of 36N	0.35%
Cyanides	Sodium hydroxide	>12 - <13	2 ml of 10N	0.080%
Phenolics	Ortho-phosphoric acid	<4 - >2	to yield desired pH	
Biological - Fish & Shellfish Tissue***	Freezing $0^{o}C$ (Dry Ice)	N.A.	N.A.	N.A.

* Sample dilution must be avoided. The volume of washings must be minimized and any dilution that does occur must be documented and the data corrected for the dilution.

** The sample may be initially preserved by cooling and immediately shipping it to the laboratory. Upon receipt in the laboratory, the sample must be acidified with conc. HNO_3 to pH<2. At time of analysis, sample container should be thoroughly rinsed with 1:1HNO_3; washings should be added to sample.

*** Dry ice is classified as an ORM-A hazard by DOT. There is no labeling requirement for samples preserved with dry ice, but each package must be plainly and durably marked on at least one side or edge with the designation ORM-A. Advance arrangements which must be met to ship dry ice are found in DOT regulation 49 CFR 173.616.

- Sample Number (specific to sampling event i.e. location)
- Type of sample, i.e., grab, 24 hour composite, etc.
- Date, Time (24 hour time is preferable, i.e., 1600 vs. 4:00 p.m.)
- Sample Location
- Preservatives
- Analytical Parameter(s)
- Collector
- Special Conditions or Remarks.

Labels and ink should be waterproof. Fix labels to containers with clear waterproof tape. Tape completely around container and over label to prevent accidental label loss or ink smear during shipping and handling.

2.7.2 Chain-of-Custody

Each sample shipment requires a chain-of-custody record. A chain-of-custody document provides a record of sample transfer from person to person. This document helps protect the integrity of the sample by ensuring that only authorized persons have custody of the sample. In addition, the chain-of-custody procedure ensures an enforceable record of sample transfer which is necessary if the sample results are to be used in a judicial proceeding alleging violations of sludge standards. This document shall record each sample's collection and handling history from time of collection until analysis as well as the information listed on each sample bottle. All personnel handling the sample shall sign, date and note the time of day on the chain-of-custody document. A sample chain-of-custody document is provided in Appendix A.

2.7.3 Sampling Log Book

All sampling activities should also be documented in a bound log book. This book duplicates all information recommended for the chain-of-custody document above, and notes all relevant observations regarding sample stream conditions.

2.8 SAFETY CONSIDERATIONS

Safety is important in sludge sampling, especially since many sampling points preclude direct collection of grab samples. Several safety considerations are noteworthy given the potential health-related effects of sewage and sludge, and the hazards associated with treatment plant equipment (water, electricity, moving components, etc.).

Personal hygiene is important for all personnel involved in sludge sampling efforts. Sludge presents a unique health hazard, not only because of the potential presence of toxic substances, but also because of the abundance of pathogens (bacteria, viruses and worms). As a precautionary measure, inoculations are recommended for all personnel who have direct contact with sludge (as well as any wastewater) samples. As a minimum, inoculation should include diseases such as typhoid and tetanus. Avoidance of direct sludge contact is preferred and is possible if proper precautions are taken. Wear rubber or latex gloves at all times, especially while collecting or handling samples, and use waterproof garments when the risk of splashing exists. Wash any cuts or scrapes thoroughly and treat immediately.

Gas production from biologically active sludge samples may cause pressure build up, especially if the samples are not stored at 4°C as recommended in Table 2.3. Treating samples with the appropriate preservatives (e.g., acids for metals samples) as

well as refrigeration will significantly suppress biological activity and therefore gas evolution. However, except for volatile and semi-volatile analysis samples, pressure may need to be periodically released to prevent explosions of the sealed sampling containers. The field control sample should also be vented to expose it to the same potential contaminants.

There are several universal safety precautions that are applicable to sludge sampling as well. When sampling sludge in confined areas, particularly around anaerobic digesters, dangerous gases may be present. These gases may include either explosive vapors (methane), poisonous mixtures (including hydrogen sulfide), or oxygen-deprived atmospheres (carbon dioxide). Explosive vapors require care to avoid sparks and possible ignition. These situations necessitate adequately ventilated equipment, gas detection meters and backup breathing apparatus. Exercise care around open pits or uncovered holes. Proper lighting increases the visibility of such hazards. Loose or dangling garments (ties, scarves, etc.) should not be worn around equipment with moving parts, especially pumps. Exercise extra awareness around pumps controlled by intermittent timers. Finally, be very careful when sampling high pressure sludge lines or lines containing high temperature, thermally-conditioned sludges (i.e., Zimpro or Porteus) in order to avoid injury by either high pressure streams or burns.

3. ANALYTICAL PROCEDURES

Sewage sludge is compositionally diverse, rich in organic matter, and highly variable in physical and chemical properties. Sewage sludge analysis is difficult because of the inherent complexity of sludge matrices. Matrix complexity often results in significant analytical interference which can lead to poor analytical accuracy and precision with a resultant loss of data reliability. For example, matrix interference, which is exacerbated in sludges, can both mask the identity of analytes by suppressing instrumental response, or falsely contribute to a positive response.

Variations in the physical and chemical properties of sewage sludge often make it difficult to obtain samples which represent the material as a whole. The diversity of sludge characteristics, coupled with the heterogeneous nature of sludges, presents a considerable challenge to precise and accurate determinations of trace levels of pollutants in sludges. Often sludge samples must be diluted to attain analytical results. A tenfold sample dilution means a tenfold increase in the detection limit (e.g., 1 ppm to 10 ppm). This increases the complexity of attaining accurate, precise data.

The following sections provide a summary of the analytical techniques available for characterization of the sewage sludge and soil constituents considered important in the selection of use or disposal options. Analytical techniques for conventional pollutants, inorganics, priority pollutant metals, priority pollutant organics, and pathogenic organisms are discussed.

3.1 CONVENTIONAL AND INORGANIC POLLUTANT PARAMETERS

Conventional pollutant parameters have historically been the focal point of sewage sludge analyses. The parameters normally associated with this group include total suspended solids, pH, oil and grease, BOD and fecal coliform. Inorganics, which have also been of concern, include phosphorus species, nitrogen species, phenolics, and total cyanide. As Table 3.1 indicates, the analytical protocols commonly employed for these analyses are adaptations of gravimetric or colorimetric techniques developed for aqueous samples.

Existing federal regulations (40 CFR Part 257) require POTWs that apply sludge to food-chain croplands to measure the pH of the sludge-soil mixture and background soil cation exchange capacity (CEC). Soil pH should be measured using a 1:1 solution of sludge-soil mixture and deionized water (see Table 3.1). For distinctly acid soils, CEC should be measured using the summation method (see Table 3.1). For neutral, saline, or calcareous soils, the sodium acetate method should be used (see Table 3.1).

Another inorganic of more recent concern is asbestos. Asbestos is a generic term which refers to naturally occurring, commercially useful fibrous silicate mineral. There are two types. Chrysotile, which comprises 93 percent of the current asbestos production, is a hydrated magnesium silicate which exhibits a much higher cancer risk for textile workers. Amphibole, which occurs in five forms, crocidolite, amosite, actinolite, tremolite and anthrophyllite, is a hydrated silica associated with various lung carcinogenic trace metals (nickel, chromium, aluminum and iron). Crocidolite poses the greatest health risk of all asbestos types and is the riskiest to miners and millers.

TABLE 3.1

ANALYTICAL TECHNIQUES FOR CONVENTIONAL AND INORGANIC POLLUTANTS IN SLUDGE

Parameter	Preparation Techniques	Analytical Technique (a)	QA/QC (b)	Aqueous Detection Limit (mg/l)	Comments	Method

In certain cases, such as when large scale asbestos removal is/will occur during the permit term or in municipalities where asbestos industries are located, the permit writer or the permittee may feel that sampling the sewage sludge for asbestos is warranted. Consult Table 2.4 for the appropriate sample sizes, containers, preservatives and holding times. Unless sample preparation will be within 48 hours, the sample should be refrigerated or stored in the dark to prevent bacterial growth.

Although there are tests which differentiate between the various asbestos types, current research does not associate health risk with specific types. The risk from asbestos is directly proportional to the concentration of airborne respirable particles. Thus current recommended analytical detection methods count fibers per area. Respirable particles are those with a diameter (length in this case) of less than 2 microns, which can only be detected using transmission electron microscopy (TEM). The polarized light microscopy (PLM) method does not detect respirable particles.

3.2 METALS

There are several analytical techniques used for the determination of metals in sewage sludge, with variations in both the sample preparation and analysis steps. A discussion of these techniques follows.

3.2.1 Analyte Isolation/Preparation Overview

Two approaches are currently used to evaluate the concentrations of metal contaminants in sludges. The most frequently used approach involves determination of the total metal content or other materials of interest, without regard to chemical form. The analytical techniques for such determinations

are designed to solubilize all of the metal species (bound to organic particulates and mineralogically bound). In the other approach, often referred to as the "leachate approach," the proportion of the total contaminant loading which will become available or mobilized under environmental conditions is determined. Thus, leachate techniques are designed to mimic a given environmental scenario. With either approach, the complexity and variability of sludge matrices has made the development of sample preparation techniques a great analytical challenge.

The two primary steps for sample preparation of metals in sewage sludge are (1) dissolution of the sample portion containing the metal components of interest, and (2) elimination of inorganic and organic interferences. The preparation procedure must be capable of effectively liberating the analytes from the solid constituents, solubilizing the elemental species, homogenizing the sample phase(s) of interest, as well as completely oxidizing the associated organics. Sludge matrices are challenging in this regard because of the high organic levels and solids loadings characteristics.

All state-of-the-art sample preparation procedures for <u>total</u> metal determinations depend on acid-mediated digestions and chemical or physical oxidation techniques. The approach involves the use of strong acid and elevated temperature digestion procedures in combination with chemical or physical oxidants. The modifications which have been used include variations in acids, oxidation reagents, physical oxidation techniques, reaction conditions, and/or the sequence in which components are employed. Acids used most frequently include nitric acid (HNO_3), hydrofluoric acid (HF), hydrochloric acid (HCL), and perchloric acid ($HCLO_4$); while hydrogen peroxide and perchloric acid are

common oxidizing reagents. High temperature (550°0C) combustion and low temperature plasma ashing (LTPA) have been used successfully as physical oxidants. Closed system digestion procedures are also used successfully.

Two closely related techniques to estimate the amount of inorganic and organic contaminants which may be leached from the sludge after disposal in landfills or surface impoundments are the Extraction Procedure protocol and the Toxicity Characteristic Leachate Procedure. In both procedures the sludge is maintained in an aqueous slurry under a given set of conditions, after which contaminant levels are measured on the filtered aqueous media. The Extraction Procedure (EP) test developed by EPA (in response to RCRA legislation) to evaluate the impact of landfill waste disposal practices on subsurface and surface waters (40 CFR Part 261 Appendix II) evaluates criteria for 8 metals and 6 pesticides. The proposed Toxicity Characteristic Leaching Procedure (TCLP) 51 Federal Register 21648 is expected to be promulgated in August/September of 1989. The TCLP test which evaluates the same 8 metals and 6 pesticides and an additional 38 compounds will replace the EP test after promulgation.

3.2.2 Analytical Techniques for Metals

3.2.2.1 Sample Preparation/Digestion

Table 3.2 shows the sample preparation/digestion technique recommended by the USEPA. Method 3050 (SW-846, 3rd ed.) is an acid digestion procedure used to prepare sediments, sludges, and soil samples for analysis by flame or furnace atomic absorption spectroscopy (FLAA and GFAA, respectively) or by inductively coupled argon plasma spectroscopy (ICAP). Samples prepared by this method may be analyzed by ICAP for all the metals listed below, or by FLAA or GFAA as indicated:

FLAA		GFAA	
Aluminum	Lead	Arsenic	Manganese
Antimony	Magnesium	Beryllium	Nickel
Barium	Manganese	Cadmium	Selenium
Beryllium	Nickel	Chromium	Silver
Cadmium	Potassium	Cobalt	Zinc
Calcium	Silver	Copper	Thallium
Chromium	Sodium	Iron	Vanadium
Cobalt	Thallium	Lead	
Copper	Tin		
Iron	Vanadium		
	Zinc		

Method 3050 prepares samples for analysis of total metals (except mercury, silver and antimony) determination through vigorous digestion in nitric acid and hydrogen peroxide followed by dilution with either nitric or hydrochloric acid. This method is not appropriate for mercury, silver, and antimony because of potential for volatilization. For the digestion and analysis procedures for mercury, silver and antimony, see section 3.2.2.2.

3.2.2.2 Analytical Detection Methods

Metals should be analyzed using either Atomic Absorption Spectrometry (AAS) or Inductively Coupled Argon Plasma (ICAP). The following discussion generally describes both methods.

Inductively Coupled Argon Plasma is a form of optical emission spectroscopy which uses an argon plasma to excite ions and atoms. This process causes the ions and atoms to emit light which is measured as a signal. The signal response is proportional to concentration level, and each element emits a uniquely characteristic light. This technique poses several advantages. A linear relationship between concentration and signal response can be expected over 4-6 orders of magnitude. Detection limits are low (although not as low as AAS, and not strongly inhibited by matrix variation); costs are moderate since

TABLE 3.2.

RECOMMENDED PREPARATION TECHNIQUE
FOR ELEMENTAL ANALYSIS OF SLUDGE SAMPLES

METHOD 3050[1]

1) Mix the sample thoroughly to achieve homogeneity. For each digestion procedure, weigh to the nearest 0.01 g and transfer to a conical beaker a 1.00- to 2.00-g portion of sample.

2) Add 10 ml of 1:1 HNO_3, mix the slurry, and cover with a watch glass. Heat the sample to 95°C and reflux for 10 to 15 min without boiling. Allow the sample to cool, add 5 ml of concentrated HNO_3, replace the watch glass, and reflux for 30 min. Repeat this last step to ensure complete oxidation. Using a ribbed watch glass, allow the solution to evaporate to 5 ml without boiling, while maintaining a layer of solution over the bottom of the beaker.

3) After Step 2 has been completed and the sample has cooled, add 2 ml of Type II water and 3 ml of 30% H_2O_2. Cover the beaker with a watch glass and return the covered beaker to the hot plate for warming and to start the peroxide reaction. Care must be taken to ensure that losses do not occur due to excessively vigorous effervescence. Heat until effervescence subsides and cool the beaker.

4) Continue to add 30% H_2O_2 in 1-ml aliquots while warming until the effervescence is minimal or until the general sample appearance is unchanged.
NOTE: Do not add more than a total of 10 ml 30% H_2O_2.

many elements may be determined at once; and analysis time is fairly rapid. The primary drawbacks are: matrix interferences (as with all analyses); the fact that solid samples cannot be analyzed directly as in AAS; and the high cost of purchasing ICAP instruments (more than $100,000).

The basic principle behind atomic absorption spectroscopy is the opposite of the emission method, ICAP. In AAS, the analyte (metal) is dissociated into atoms in a flame or furnace, and passed through a light beam from the reference source. This reference source emits a beam of the characteristic atomic spectrum of the analyte. The analyte in the sample will absorb this energy thus decreasing the original signal to the detector from the reference beam. Since absorption is directly proportional to concentration, the analyte concentration can be determined. Selection of a specific wavelength which corresponds to one of the more intense characteristic line of the analyte's spectra allows for high element specificity. For this reason, AAS is more responsive than ICAP to lower concentrations of metals in sludge. However, this very precise nature of AAS is also the cause of its major drawback: only one elemental determination per sample is possible at a time. Thus, the total analysis time of AAS is significantly greater than that of ICAP when many metals are present in the sample.

In sewage sludge applications, it is important to realize that both of these analytical techniques are reliable tools and neither offers a significant technical advantage over the other. However, ICAP's capability to simultaneously analyze multiple elements is a tremendous advantage in terms of sample throughput and labor savings, which may outweigh the noted limitations. For sludge applications, EPA recommends either method and leaves the

final decision to individual POTWs. Table 3.3 summarizes the relative advantages and disadvantages of ICAP and AAS.

ICAP Method 6010

EPA recommends Method 6010 for the determination of metals in solution by Inductively Coupled Argon Plasma atomic emission spectroscopy (ICAP). This method can be found in the USEPA manual "Test Methods for Evaluating Solid Waste," (SW-846, Nov. 1986, 3rd Ed., Vol 1A, pp. 6010-1,7). The method is applicable to a large number of metals and wastes. All matrices, including ground water, aqueous samples, EP extracts, industrial wastes, soils, sludges, sediments, and other solid wastes, require digestion prior to analysis. EPA recommends digestion Method 3050 (SW-846, 3rd Ed. - see Section 3.2.2.1).

Elements for which Method 6010 is applicable are listed in Table 3.4. Detection limits, sensitivity, and optimum ranges of the metals will vary with the matrices and model of spectrometer. The data shown in Table 3.4 provide concentration ranges for clean (interference-free) aqueous samples. Due to matrix interferences, the detection limits in typical sludge samples will be somewhat higher. Use of this method is restricted to spectroscopists who are knowledgeable in the correction of spectral, chemical, and physical interferences.

Atomic Absorption Methods

EPA recommends use of the methods listed in the manual "Test Methods for Evaluating Solid Waste" (SW-846, Nov. 1986, 3rd Ed., Vol 1A) for the determination of metals in solution by atomic absorption spectroscopy. A complete set of procedures for each metal-specific method may be found on pages 7000-1 to 7950-3. These methods are simple, rapid, and applicable to a large number of metals in drinking, surface, and saline waters as well as domestic and industrial wastes. Ground water, aqueous samples other than drinking water, EP extracts, industrial wastes, soils, sludges, sediments, and other wastes require digestion prior to analysis. EPA recommends digestion Method 3050 (SW-846, 3rd Ed. - see section 3.2.2.1).

Detection limits, sensitivity, and optimum ranges of the metals will vary with the matrices and models of atomic absorption spectrometers. The data shown in Table 3.5 provide some indication of the detection limits obtainable by direct aspiration and by furnace techniques. Due to the matrix

[1] For drinking water and other non-sludge applications, priority pollutant scans may require very low contaminant detection levels. Therefore, there may be no choice except to rely on the lower detection limit capability of graphite furnace AAS. This, in turn, will determine the digestion method used.

d Cold vapor technique.

interferences, the detection limits for typical sludge samples will be somewhat higher.

Mercury Analysis

The physical-chemical characteristics of mercury are not amenable to digestion by the generally recommended technique, Method 3050. For the determination of total mercury (organic and inorganic) in soils, sediments, bottom deposits, and sludge material, EPA recommends using Method 7471, a cold-vapor atomic absorption spectrometry. This method appears in the EPA manual "Test Methods for Evaluating Solid Waste." (SW-846, Nov. 1986, 3rd Ed., pp. 7471-1,10). Prior to analysis, the solid or semi-solid samples must be prepared according to the procedures discussed in this method. The typical detection limit for this method is 0.0002 mg/L.

Antimony and Silver Analysis

The procedures for preparation of antimony and silver samples are given in Method 3005. Method 3005, a soft digestion, is presently the only digestion procedure recommended for antimony. It yields better recoveries than either Method 3010 or 3050. There is no hard digestion for antimony at this time (SW-846, Nov. 1986, 3rd Ed., p. 7041-2). Samples prepared by Method 3005 are amenable to determination by either ICAP Method 6010 or the atomic absorption furnace technique, Method 7041. (SW-846, 3rd Ed. - see pp 7041-1 through 7041-4). Detection limits for Method 7041 are 3 ug/L for antimony and 10 mg/l for silver.

3.3 ORGANICS

The evolution of analytical techniques for organic contaminants has involved a number of modifications to a basic method in order to widen potential applications. Because the instrumentation is complex and the number of possible analytes is large, quality control is difficult to monitor and several analytical techniques are required. As with analyses for metals and other elements, the organic-rich complex matrices characteristic of sewage sludges often mean that analyte extraction/isolation procedures play a significant role in the reliability of the resultant analytical data.

3.3.1 Overview of Analyte Extraction and Isolation

For a number of reasons, EPA has focused regulatory attention on two categories of contaminants: volatile organics and semi-volatile organics. While the classification of these groups is founded upon inherent physical/chemical properties, extraction and isolation techniques are the functional basis for the distinction.

Volatile Organics

Two methods are available for extraction and isolation of volatile organics in aqueous and solid matrices: headspace techniques and purge and trap techniques. Several versions of these procedures have been sanctioned by regulatory agencies and/or developed for use in specific applications. For POTW sludge sampling and analysis, EPA recommends two analytical methods (1624C, 624-S) which both extract via purge and trap (see Section 3.3.2).

Purge and trap requires moderate sample preparation. The method relies upon a stripping process in which an inert gas is bubbled through the sample to remove the volatile organics. The volatilized organics are transferred from the aqueous/solid phase to the gaseous phase and subsequently trapped on a solid adsorbent column. The adsorbent column is then heated and the trapped organics are thermally desorbed and swept into the analytical instrument.

Semi-volatile Organics

The first step in all procedures for determination of semi-volatile organics is solvent extraction. (Note: For extraction procedures recommended by EPA for sludge analysis see Section 3.3.2). The sample material is mixed and agitated with a solvent, causing the organic analytes to be preferentially partitioned into the solvent phase. Extractions are typically performed at both acidic and basic pH ranges to facilitate extraction of ionizable organics. Modifications to the extraction method are usually based upon the manner in which the sample-solvent mixture is agitated and post-extraction cleanup procedures.

The organic solvent used most frequently for extraction of semi-volatile analytes is methylene chloride, either singly or in combination with a more polar solvent. Extraction techniques which are applicable to sludge and solid matrices include:

- Sonication extraction
- Continuous liquid-liquid extractors
- Soxhlet extraction
- Mechanical agitation (shaker table, homogenization, or wrist-action shaker).

Sonication relies on the mechanical energy developed from ultra-sonic devices to affect agitation and solvent-solid contact. The best approach involves the use of a sonication horn which is immersed into the solvent-sample mixture, rather than a sonication bath. This technique has also been proven effective in sludge and sediment applications.

Continuous liquid-liquid extractors and Soxhlet extractors employ the same basic principle of operation. The extraction solvent is distilled from a reservoir, condensed above the sample material, and subsequently rains down through the sample. The distillation-condensation process continues until a volume of solvent has collected sufficient force to establish a siphon, at which point the extraction solvent is siphoned back into the reservoir. The cycle is repeated with freshly distilled solvent and is generally allowed to occur for 12-24 hours. The continuous liquid-liquid extraction procedure can only be used on low solids (<5%) sludges, while the Soxhlet technique is most useful for materials with low water content.

A variety of mechanical agitation techniques have been used for extractable organics determinations, including homogenization, wrist-action shakers and platform shakers (shaker tables). The objective of each technique is to maximize the contact between the extraction solvent and the solid particles. Wrist-action and platform shakers have both proven adequate, with wrist-action shakers generally preferable for smaller sample containers and platform shakers preferable for larger extraction vessels. Homogenization relies on agitation of the solvent-solid mixture, rather than agitation of the entire extraction vessel. This technique has been used quite successfully in sludge applications as a result of its superior agitation. However,

sand, a fairly common constituent of sewage sludge, literally chews up high speed homogenizers.

As a result of the complexity of sludge matrices, fractionation and/or cleanup procedures are often required after sample extraction to minimize interference. The basic concept used in virtually all cleanup techniques is selective adsorption of the interfering components. Although a variety of cleanup procedures have been developed for specific analytes, the techniques commonly employed for the listed applications include:

- Gel permeation resins - broad spectrum cleanup and higher molecular weight biogenic organics
- Activated carbon - fractionation and general purpose cleanup
- Alumina adsorbent - inorganic adsorbent
- Florisil adsorbent - inorganic adsorbent
- Silica gel adsorbent - inorganic adsorbent
- Copper and mercury - removal of sulfur-containing compounds.

Cleanup procedures can be used individually or in combination with other procedures, depending upon the need of the particular application and the complexity of the sample.

For more detail regarding extraction and isolation techniques, consult the references cited in 40 CFR Part 136, "Guidelines for Establishing Test Procedures for the Analysis of Pollutants."

3.3.2 Recommended Analytical Techniques for Organics

For determining concentrations of organic pollutants in sludge, EPA recommends two methods designed for qualitative and quantitative analysis of municipal and industrial wastewater treatment sludges:

- Volatile Organics - 624-S (EPA 1984b) or 1624C (EPA 1988a)
- Semi-Volatile Organics - 625-S (EPA 1984b) or 1625C (EPA 1988a)

Each of these two methods employ gas chromatography/mass spectrometry (GC/MS).

GC/MS is a combination of two microanalytical techniques: gas chromatography (a separation technique) and mass spectrometry (an identification technique). A sample aliquot is prepared for extraction, extracted, then introduced to the GC/MS system. The extract is vaporized quickly at an elevated temperature and carried by an inert gas (mobile phase) through a coated column (stationary phase). Separation of the extract components is effected by their differential partitioning between stationary and mobile phases. The separated components exit the column and enter the mass spectrometer (MS) where they are decomposed to specific unimolecular species. The manner in which a component fragments is characteristic of that component and is the basis for identification. The MS detector quantifies a compound by responding with a signal proportional to the detected amount of the compound.

The GC/MS system is calibrated by measuring signal response to three to five analyte standard solutions of various concentrations (e.g., 20-160 ng/ml). The solutions are carefully

prepared mixtures of pollutants suspected to be present in the sample, as well as a few labeled pollutant analogs known as internal standards. The accumulated measurements form an instrument response curve. Samples are spiked with the same internal standards at a fixed concentration immediately prior to analysis. If the MS detects any sample-originated pollutants, the generated signal for each pollutant is measured against both the internal standard and the response curve.

GC/MS analysis affords several advantages over other techniques:

- Provides qualitative and quantitative information about a wide range of organic compounds.
- Confirms specific information from a small sample size.
- Produces a spectrum with a fragmentation pattern, or fingerprint, which can be used to identify an unknown.

3.3.2.1 Methods 1624C and 1625C

Methods 1624C and 1625C are draft methods for analyzing volatile organics (Method 1624C) and base/neutral, non and semi-volatile organics (Method 1625C) in sludge. These methods were developed by the USEPA Office of Water Industrial Technology Division, and are derived from previous methods 1624 and 1625 (see 40 CFR Part 136) for analyzing wastewaters.

The 1624C/1625C (and 1624/1625) test procedures are isotope dilution techniques. In conventional GC/MS, up to six internal standards are used to quantify the response of perhaps several dozen analytes. Isotope dilution GC/MS employs stable, isotopically labeled analogs of the compounds of interest, which is analogous to providing a separate internal standard for each analyte. The result is that isotope dilution GC/MS is sensitive

to even minute contaminant concentrations. Methods 1624C/1625C and 1624/1625 are similar in this respect but differ in sample preparation.

Method 1624C sample preparation for sludge samples consists of the following three routes, depending on the percent (%) solids content of the sludge. If the solids content is less than one percent, stable isotopically labeled analogs of the compounds of interest are added to a 5 gram sample and the sample is purged in a chamber designed for soil or water samples. If the solids content is 30 percent or less, the sample is diluted to one percent solids with reagent water, and labeled compounds are added to a 5 gram aliquot of the sludge/water mixture. The mixture is then purged. If the solids content is greater than 30 percent, five ml of reagent water and the labeled compounds are added to a 5 gram aliquot of sample. The mixture is then purged.

Method 1625c sample preparation for sludge samples consists of the following three routes, depending on the percent (%) solids content of the sludge. If the solids content is less than one percent, a one liter sample is extracted with methylene chloride using continuous extraction techniques. If the solids content is 30 percent or less, the sample is diluted to one percent solids with reagent water, homogenized ultrasonically, and extracted. If the solids content is greater than 30 percent, the sample is extracted using ultrasonic techniques. Each extract is subjected to a gel permeation chromatography (GPC) cleanup.

These methods are currently undergoing revision at EPA's Environmental Monitoring and Support Laboratory for problems relating to the sample preparation portions. They are the

methods used in the National Sewage Sludge Survey (which EPA is conducting to provide a current data base to be used to set pollutant limits, evaluate risks of use and disposal practices, and evaluate the impacts of the proposed rule) and also are discussed in the 40 CFR Part 503 regulation proposed on February 6, 1989 and now out for comment. Depending on the results of the comment period, the isotope dilution methods may be exclusively required for priority pollutant organics analysis when 40 CFR Part 503 is finalized.

3.3.2.2 Methods 624-S and 625-S

Methods 624-S and 625-S are existing methods for the measurement of organic priority pollutants in sludges. These test procedures were derived from previously developed methods 624 and 625 for analyzing wastewaters (see 40 CFR Part 136). The 624-S/625-S techniques are conventional GC/MS and operate as described in Section 3.3.2. Method 624-S is used to analyze for volatile organic compounds. Method 625-S is used for semi-volatile or nonvolatile organics.

In Method 624-S, an inert gas is bubbled through a 10-ml sludge aliquot contained in a purging chamber at ambient temperature. The purgeable compounds are transferred from the aqueous phase to the vapor phase. The vapor is carried through a sorbent column where the purgeables are trapped. After purging is completed, the sorbent column is heated and backflushed with the inert gas to desorb the purgeables into a gas chromatographic column. The gas chromatograph is temperature programmed to separate the purgeables which are then detected with a mass spectrometer.

Method 625-S uses repetitive solvent extraction (see section 3.3.1) aided by a high-speed homogenizer. The extract is

separated by centrifugation and removed with a pipette or syringe. Extracts containing base/neutral compounds are cleaned by silica gel or florisil chromatography or by gel permeation chromatography (GPC). Extracts containing the acidic compounds are cleaned by GPC. The organic priority pollutants are determined in the cleaned extracts by capillary column or packed column GC/MS. Option A, i.e., extract cleanup by silica gel or florisil chromatography and analysis by capillary column GC/MS (HRGC/MS) is preferred since HRGC/MS allows easier data interpretation.

While Methods 1624C/1625C provide lower detection limits, in some cases, than Methods 624-S/625-S, these methods are also more costly. Presently, Methods 1624C/1625C cost about $2,200-$2,400 per sample, which is approximately $200-$400 more than a similar analysis by Methods 624-S/625-S. The extra cost reflects the Method 1634/1635 isotope spikes and approximately two weeks of work necessary to prepare additional spectral libraries.

Neither Methods 624-S/625-S or Methods 1624C/1625C detect pesticides at very low concentrations. Without megabore column analysis, which may cost an additional $1,000, none of these methods will do better than the detection limits, 20-50 ppb. For some highly mixed pesticides such as chlordane, these methods can only detect 200-300 ppb. At this time, EPA is not recommending megabore column pesticide analysis nationally. However, in situations where lower detection limits are crucial such as in PCB or pesticide analysis, megabore column analysis is necessary.

3.4 PATHOGENIC MICROORGANISMS

A pathogen or pathogenic agent is any biological species that can cause disease in the host organism (primarily humans). These organisms fall into four broad categories: viruses,

bacteria, parasites, and fungi. From these categories, species commonly found in sewage sludge include fecal coliforms, fecal streptococci, salmonella, and ascaris (helminth). Wastewater sludge disinfection, the destruction or inactivation of pathogenic organisms in the sludge, is carried out to minimize public health concerns regarding these and other microbial agents.

The 40 CFR Part 257 regulations issued under joint authority of Subtitle D of the Resource Conservation and Recovery Act (RCRA) and Section 405(d) of the Clean Water Act establish requirements for the disposal of solid waste which include pathogens in sewage sludge. The regulations (40 CFR Part 257.3-6) require that sewage sludges applied to the land surface or incorporated into the soil be treated by a Process to Significantly Reduce Pathogens (PSRP). Public access must be controlled for at least twelve months after sludge applications and grazing by animals whose products are consumed by humans must be prevented for at least one month after application. Treatment by a Process to Further Reduce Pathogens (PFRP) is required for sewage sludge applied to the land surface or incorporated into the soil if crops for direct human consumption are grown within eighteen months after application, if the edible portion of the crop will touch the sludge.

Rather than requiring a specific reduction or concentration for given pathogens, the process-based regulation (see Appendix II of 40 CFR Part 257) describes and sets numerical requirements for unit processes and operating conditions that qualify as PSRP and PFRP (e.g., criteria for process time and temperature and for volatile solids reduction). Thus permit compliance is based on meeting process requirements, not pathogen reduction per se. Appendix II of 40 CFR Part 257 allows methods or operating

conditions other than those listed under PSRP or PFRP if pathogens and vector attraction are reduced commensurate with the reductions attainable from listed methods. Appendix II (of 40 CFR Part 257) does not prescribe the operation mode (i.e., batch or continuous) for digesters. The regulation also does not specify a method for calculating volatile solids reduction. For a comprehensive discussion of the ways that volatile solids reduction may be calculated and their limitations, refer to Appendix B of this guidance document.

Although the 40 CFR Part 257 regulations are based on specific processes rather than on meeting specific pathogen reduction levels, the regulations do provide that other processes "may be acceptable if pathogens are reduced to an extent equivalent to the listed processes." In order to provide guidance on the equivalence of these other methods EPA has a panel of experts, the Pathogen Equivalency Committee (PEC), which evaluates the acceptability of the process based on the level of pathogen reduction, as determined by standardized analytical tests. For more comprehensive information on pathogen and guidance on whether alternative processes provide equivalent levels of pathogen reduction consult the draft "Guidance for Controlling Pathogens in Municipal Wastewater Sludge" PEC/EPA May 1989 (to be finalized July/August 1989).

Sampling techniques for determining pathogens in sewage sludge are no different than for other tests except that no preservatives are used. In the absence of definitive sludge methods for determining bacteria concentrations, modified standard wastewater methods are often utilized. The analytical methods for analysis of pathogens and indicator organisms are provided in Table 3.6. Unfortunately no standardized methods exist for parasitic determinations.

TABLE 3.6

ANALYTICAL TECHNIQUES FOR DETERMINATION OF PATHOGENIC MICROORGANISMS IN SEWAGE SLUDGE

Pathogen	Preparation Technique	Culture Media	Reference
Fecal Coliform		---	A(908 or 909)
Fecal streptococcus/ enterococci		---	A(910A) or B
E. Coli	Centrifugation and filtration	M-PC broth membrane filters	A(912E)

The effectiveness of many PSRPs and PFRPs for reducing pathogens can be estimated by measuring the effects on fecal indicator organism densities (e.g., fecal coliform and/or fecal streptococcus). These tests are less expensive and easier to run than tests for specific pathogens and also provide good control data.

4. QUALITY ASSURANCE/QUALITY CONTROL

An essential part of a sampling and analysis program includes a well designed quality assurance/quality control (QA/QC) program. The extent of the QA/QC program should mirror the intent and purpose of the sampling effort. It should be noted that the facility is ultimately responsible for the quality of the data even if a contractor is used. Therefore, it behooves the POTW to have a good QA/QC program.

If the purpose of the sampling and analysis program is to determine compliance with permit conditions, or to provide critical data for making a major cost decision, then the QA/QC program should be extensive and be able to demonstrate the precision, accuracy, representativeness, comparability and completeness of the data. The determination of these QA/QC parameters and their definitions are as follows:

- QA is an overall program which guarantees the quality of the product. It includes a QC auditing process to prevent future defects. QA is synonymous with process control, continuous improvement and prevention of poor quality. QC is the examination of the product to determine if it meets the specifications of the QA program. QC is part of the overall QA program. QC is synonymous with appraisal after the fact. An example of QC is that lab duplicate results must be within a certain percentage of each other or else the whole batch must be redone.

- Laboratory QA includes prevention of data contamination during laboratory procedures. Contamination may be due to various other tests that are run in the lab at any given time. In order to assure that any sample contamination that does occur does not contaminate lab data, a lab QA sample, usually a deionized water "blank" (or other "clean" appropriate material), is run along with the actual field samples. Lab QA also includes doing duplicates and spikes of the actual samples. Field QA serves the same purpose, to prevent data from being erroneous. However, it is virtually

impossible to prevent contamination of the samples since the sampling environment is not controllable. Therefore, the field blanks are subject to the same conditions as the samples, i.e., the containers are exposed to the environment as long as the sample containers are open, the sample and field "blank" are transported together.

- Accuracy, which is closeness to actual values, of all sample testing and analyses should be evaluated at a minimum frequency of 5 percent of the samples tested (i.e., at least one in every 20 samples), using spiked samples. Accuracy is calculated from the known and analytically derived values of spiked parameters, and expressed as percent recovery. The accuracy required in the quality assurance program for the analyses is specified in each of the EPA methods (e.g., EPA 600 or 1600 Series or EPA Methods for Chemical Analysis of Water and Wastes).

- Precision, which is repeatability of results, of sample analyses should be evaluated at a minimum frequency of 5 percent (i.e., at least one in every 20 samples), using spiked samples in duplicate. Precision is calculated from the analytical results of the spiked analytes in each set of duplicate samples, and expressed as percent relative standard deviation. The precision required in the quality assurance program for the analyses is specified in each of the EPA Methods (e.g., EPA 600 or 1600 series or EPA Methods for Chemical Analysis of Water and Wastes).

- Completeness is calculated as the ratio of valid measurements obtained to the number of valid measurements needed to reach a predefined statistical level of confidence in the resulting data. Completeness is determined and evaluated on the basis of data sets for each specific measurement process. Data are considered to be valid if both the accuracy and precision of the measurements meet the data quality objective (i.e., accuracy, precision, and compliance with analysis method protocol).

- All sampling should be performed using methods, procedures, and controls that ensure the collection of representative samples which thus ensures that the analytical results are representative of the media and the conditions being measured.

- Comparability is a more qualitative QA measurement. All analytical data must be calculated and reported in units consistent with those specified in the applicable permit. Previously developed data generated for each facility about to be inspected is reviewed to ensure that no difficulties of data comparability will be encountered by following the specifications of the permit. If no previous data exist and the permit requirements are incomplete or ambiguous, data should be reported in the standard units prescribed in the appropriate EPA Methods (e.g., EPA 600 or 1600 series or EPA Methods for Chemical Analysis of Water and Wastes).

These QA/QC procedures are necessary for ensuring data quality. On the other hand, if the purpose of the sampling effort is to monitor plant performance for routine operation and maintenance (O&M) decisions, a simplified QA program that includes sample replicates and a field blank might suffice.

Sludge sampling and analysis programs for determining compliance with permit conditions should include a written QA Plan. EPA guidance for the development of a QA Program (EPA Quality Assurance Project Plans (QAPP), 1983) identifies 16 elements which should be addressed in a QA plan:

Title Page

Table of Contents

Project Description

Project Organization and Responsibility

QA Objectives for Measurement Data in Terms of Precision, Accuracy, Completeness, Representativeness, and Comparability

Sampling Procedures and Frequency

Sample Custody

Calibration Procedures and Frequency

Analytical Procedures

Data Reduction, Validation and Reporting

Internal Quality Control Checks

Performance and System Audits

Preventive Maintenance

Specific Routine Procedures Used to Assess Data Precision, Accuracy and Completeness

Corrective Action

Quality Assurance Reports to Management

In preparing a QAPP, the QA parameters and specifications of the analytical program should be dictated by the analytical parameters. The QA parameters are specified in each analytical protocol. There are situations (particularly for enforcement actions) in which more stringent protocols will be desired.

In preparing the QA plans, the collection of field blanks (blanks to reflect sample handling effects) and sample replicates should be addressed. At a minimum, field blanks should be collected every day that sampling is performed. Field blanks should be prepared at the beginning of each sampling event, at each discrete sampling site, by pouring American Society for Testing and Materials (ASTM) Type II reagent-water into prepared sample bottles. These sample bottles are randomly selected from the supply of prepared sample bottles; a sample container should be selected that is appropriate for each type of analysis for which environmental samples are being collected (see Table 2.4). The field blanks should be handled and analyzed in the same manner as environmental samples. Because field blanks and environmental samples are collected under the same conditions, field blanks analyses should be used to indicate the presence of

external contaminants that may have been introduced into samples during collection.

One field replicate for every 20 samples or less should be collected at a preselected POTW monitoring point. Field replicates should be collected at the same time and in the same manner as the other environmental samples. Results of the field replicate analyses should be used primarily to assess the precision of the field sampling methods.

In preparing and evaluating the analytical report, attention should be given to the data quality, and the impact of both the sampling and analysis data quality to the overall interpretation of the analytical results. Both the data from the field QA samples and the laboratory QA samples should be evaluated for the presence of contaminants. Additionally, statistical procedures should be used for the determination of precision, accuracy and completeness. The QAPP 1983 document provides a description of the statistical procedures and their applications. All reports of analytical data should contain a separate section which assesses the quality of the reported data.

The sample procedures and frequency section of the quality assurance plans should address, among other elements, sample holding times, sample preservation procedures, and sample chain-of-custody. Maximum sample holding times are presented in Table 2.4. Section 2.5.3 addresses sample preparation. Section 2.7.2 addresses sample chain-of-custody.

The section of the quality assurance plan on internal quality control checks specifically discuss how the following activities will be addressed:

Organic Priority Pollutants

- Instrument tuning and calibration
- Method blank analysis
- Surrogate spike analysis
- Matrix spike/matrix spike duplicate analysis
- Internal standards analysis

Inorganic Priority Pollutants

- Initial calibration verification
- Continuing calibration verification
- Instrument response and linearity verification
- Calibration and preparation blank analyses
- Interference check sample analyses
- Spike sample analyses
- Duplicate sample analyses
- Quality control sample analyses
- Serial dilution analyses (if applicable)
- Instrument detection limit determination
- Method of standard additions application.

5. SAMPLING AND ANALYTICAL COSTS

The cost of carrying out a sludge sampling program can vary depending on the number and type of samples, parameters analyzed, and whether analytical services are contracted out. The following discussion examines sampling and analytical costs as of April 1989.

5.1 MANPOWER REQUIREMENTS

Manpower requirements fall into two categories: (1) supervisory and program development, and (2) sampling/analytical. All sampling programs should be designed and supervised by qualified personnel. Developmental and supervisory needs will vary according to the following factors:

- Type and number of samples
- Number of streams to be sampled
- Number of facilities/locations
- Availability of suitable sample points
- Parameters to be analyzed
- Experience and qualifications of field and laboratory personnel.

The number of factors influencing supervisory needs makes estimating average costs for these needs impractical. Costs will vary according to the hours needed for each program and according to the salary range of qualified personnel within a given organization.

Sampling manpower needs will also vary widely depending on the conditions listed above. For 24-hour composite sampling, a

two shifts (more likely three) are required. The actual time spent sampling during the shifts will depend on how frequently grab samples are collected (one per hour or once every 4 hours) during the 24-hour sampling period. In addition to the manpower required to actually collect the sample, additional time is required for sample preparation and handling. On-the-job training is generally acceptable for sampling procedures.

Estimates of some of these needs are presented below:

TABLE 5.1

Activity	Manpower
o Automatic Sampler Setup[1]	0.5 - 4 manhours
o Sample Container Preparation[2]	2 - 15 man-minutes / sample
o Sample Documentation[3]	2 - 15 man-minutes / sample
o Sample Handling[4]	2 - 60 man-minutes / sample

1 Depending on sample point characteristics.
2 Depending on parameter.
3 Depending on parameter, ultimate data use and number of points sampled simultaneously.
4 Depending on parameters sampled and whether samples are analyzed on site, are delivered or shipped.

5.2 IN-HOUSE ANALYTICAL COSTS

If any analytical work is done in-house, manpower, equipment/facility and operating (i.e., electrical, chemical supplies, etc.) costs will be incurred. Real costs will vary according to what extent the analytical load imposed by the sludge sampling is marginal to the laboratory's operational

capacity. Two extremes serve as examples of this cost variability.

A plant electing to do in-house analysis which has no laboratory would need to make a sizable expenditure for an adequate facility and the necessary analytical equipment and supplies. In addition, qualified (B.S. Chemistry or equivalent) laboratory personnel must be put on the payroll. Given these circumstances, it would generally not be practical to do in-house analysis. Instead, it is likely that this plant would contract out for analytical services.

A second plant, conducting a similar sludge sampling program, also elects to do all related analytical work in-house. This plant, however, has an analytical laboratory in place which is capable of performing all analyses required. In addition, the laboratory is presently operating below capacity. The additional load imposed by the sludge sampling program will not require any capital expenditure, and will require little, if any, additional laboratory manpower (any additional manpower needs can be accommodated by limited overtime rather than new employee hires). In the case of this plant, in-house analysis for a sludge sampling program can be accomplished at a very low real cost.

Because of the wide range of real costs possible for sampling and in-house analytical work, no attempt is made herein to quantify these costs on a dollars per sample basis. Rather, each sampling program must be analyzed in light of applicable salary scales, sampling program complexity and in-house analytical capabilities.

5.3 CONTRACT ANALYTICAL COSTS

Many sludge sampling programs, particularly those conducted by small municipalities or authorities, will utilize contract laboratories for analytical work. In contrast to sampling costs, which vary greatly due to a wide variety of factors, contract analytical costs fall within a relatively narrow range. Table 5.2 presents typical analytical costs for parameters commonly run on sludge samples. These cost estimates were obtained in a March 1988 and 1989 telephone survey of analytical laboratories.

Two factors must be considered in estimating contract analytical costs for sludge sampling programs. The first is the need, depending on parameters, for additional preparation of sludge samples prior to analysis. Many laboratories charge an additional fee for this preparation, which can be as much as $100, depending on the parameters to be run.

The second factor impacting analytical costs is the practice by most laboratories of offering discounts on per sample prices for multiple sample analysis. These discounts vary from laboratory to laboratory, and can be substantial depending on the number of samples involved. Of particular importance is the number of samples being received simultaneously by the laboratory (i.e., a greater discount will typically be offered for 10 samples if all are to be analyzed at one time rather than if one is to be delivered to the lab each week for 10 weeks).

5.4 SAMPLING EQUIPMENT COSTS

The cost of sampling equipment and containers is typically a relatively small fraction of the overall cost of a sludge sampling program. In general, the manual collection methods used for sludge sampling require only simple, relatively inexpensive

4 herb.			150	175
TOTAL EP	$ 420		$490	$585

equipment. The following paragraphs highlight the primary equipment cost items in a typical sludge sampling program.

- **Sample Containers** - Sample container costs are related to: (1) the number of containers needed, and (2) the type of container needed, depending on parameter(s) to be analyzed. The following are typical per-container prices for some commonly used containers:

Container	Size	Approx. Price
Teflon	1 liter	$ 35 - 40
Graduated Glass (w/Teflon-lined cap)	1 liter	$ 3 - 4
Polypropylene	1 liter	$ 2
Polypropylene	0.5 liter	$ 1.50
Polypropylene	10 liter	$ 15
Glass (w/Teflon lined cap)	0.5 liter	$ <1 - 2

  As with analytical costs, suppliers of containers often offer substantial discounts for volume purchases.

- **Automatic Samplers** - In most sludge sampling programs the use of automatic sampling equipment will be precluded due to sample characteristics. If automatic sampling is utilized in a given sampling program, automatic sampler costs will typically constitute the majority of sampling equipment costs. Portable, battery-powered peristaltic-type samplers typically cost from $1000 to $3000, depending on features such as computerized controls, etc. Pneumatically operated plunger-type samplers will vary in price according to application and capacity.

- **Manual Sampling Equipment** - In general, equipment costs for manual sludge sampling are minimal. Stainless steel pitchers (2 liter), which are useful for sampling from either a tap or an open channel flow, are available for approximately $20. Polypropylene pitchers typically cost about 1/2 of the price of stainless steel. Stainless steel scoops used for sludge cake sampling cost approximately $40 (depending on size), while aluminum scoops of similar size are available for less than $10.

- **Preservatives** - Reagent grade chemicals should be used as preservatives. Since each sample will typically

require very small amounts of preservatives, cost on a per sample basis is negligible.

5.5 OPPORTUNITIES FOR COST SAVINGS

To provide a representation of sludge quality over a fixed duration, sewage sludge can be composited (i.e. mixed), reducing the number of samples to be analyzed. In light of the high costs associated with analysis of priority pollutant organics in sewage sludge, compositing samples provides an opportunity to substantially lower analytical costs. Field compositing is not an appropriate technique to use when the sample will be analyzed for volatile components. Lab personnel can composite grab samples in the lab.

When interested in daily variation in sludge constituents, a POTW can collect and analyze 24-hour composite samples, each consisting of six or more grab samples. This represents a significant cost savings when compared to separately analyzing many individual, non-composited samples. Smaller POTWs, with less variation in sludge quality, may elect to composite samples over several days as opposed to 24-hour composites. The suitability of a multi-day compositing procedure will depend upon whether the specific sludge constituent can be adequately preserved in the sludge sample. Table 2.3 shows the recommended preservatives and maximum sample holding times for organic and metal pollutants.

Another way to reduce costs would be to sample more frequently for parameters that are relatively inexpensive to analyze such as metals, nitrogen, phosphorus, and potassium, and to test for organic pollutants (expensive) less frequently, so long as some data are available indicating that the levels of organic contaminants in the sludge are acceptable.

APPENDIX B

DETERMINATION OF VOLATILE SOLIDS

DETERMINATION OF VOLATILE SOLIDS REDUCTION IN DIGESTION[1]

By J.B. Farrell

INTRODUCTION

When sewage sludge is utilized on land, Federal regulations require that it be treated by a "process to significantly reduce pathogens" (PSRP) or a "process to further reduce pathogens" (PFRP). A requirement of both of these steps is a reduction in "vector attraction" of the sludge. If the PSRP or PFRP is anaerobic or aerobic digestion, the requirement for vector attraction reduction is achieved if volatile solids are reduced by 38 percent. As Fischer[1] has noted, the Federal regulation[2] does not specify a method for calculating volatile solids reduction. Fischer observed that the United Kingdom has a similar requirement for volatile solids reduction for digestion (40 percent), but also failed to prescribe a method for calculating volatile solids reduction. Fischer has provided a comprehensive discussion of the ways that volatile solids reduction may be calculated and their limitations. He presents the following equations for determining volatile solids reduction:

1. Full mass balance equation
2. Approximate mass balance equation
3. "Constant ash" equation
4. Van Kleeck equation

The full mass balance equation is the least restricted but requires more information than is currently collected at a wastewater treatment plant. The approximate mass balance equation assumes steady state conditions. The "constant ash" equation requires the assumption of steady state conditions as well as the assumption that ash input rate equals ash output rate. The Van Kleeck equation, which is the equation generally suggested in publications originating in the United States[3] is equivalent to the "constant ash" equation. Fischer calculates volatile solids reduction using a number of

[1] Source: "Control of Pathogens in Municipal Wastewater Sludge," EPA, to be published August, 1989.

examples of considerable complexity and illustrates that the different methods frequently yield different results. He closes with the recommendation, obviously directed to rulemakers, that "if it is necessary to specify a particular value for FVSR (fractional volatile solids reduction) then the specification should indicate the method of calculation of FVSR."

Fischer's paper is extremely thorough and is highly recommended for someone trying to develop a deep understanding of potential complexities in calculating volatile solids reduction. However, it was not written as a guidance document for field staff faced with the need to calculate volatile solids reduction in their own plant. The nomenclature is precise but so detailed that it makes comprehension difficult. In addition, two important troublesome situations that complicate the calculation of volatile solids reduction--grit deposition in digesters and decantate removal--are not explicitly discussed. Consequently, this presentation has been prepared to present guidance that describes the major pitfalls likely to be encountered in calculating volatile solids reduction and assists the practitioner of digestion to the best route to take for his situation.

The recommendation of this presentation is not the same as Fischer's. He suggests that the authorities should have provided a calculation method when they required specific volatile solids reductions. From a review of Fischer's results and this presentation, it will be clear that sometimes very simple calculations will give correct results and in other cases the simple methods will yield results seriously in error. Selecting one method and requiring that it be followed is excessively restrictive. The best solution is to require that the calculation be done correctly and then provide adequate guidance. This presentation attempts, belatedly, to provide that adequate guidance.

It is important to note that the calculations of volatile solids reduction will only be as accurate as the measurement of volatile solids content in the sludge streams. The principal cause of error is poor sampling. Samples should be representative, covering t'e entire charging and withdrawal periods. Averages should cover extended periods of time during which changes in process conditions are minimal. For some plants it is expected that

periodic checks of volatile solids reduction will produce results so erratic that no confidence can be placed in them. In this case, adequacy of stabilization can be verified by the method suggested in the text--periodically batch digest the product for 40 days. If VS reduction is less than 15%, the product is sufficiently stable.

The Equations for FVSR

The equations for fractional volatile solids reduction (FVSR) that will be discussed below are the same as developed by Fischer[1], except for omission of his "constant ash" equation. This equation gives identical results to the Van Kleek equation so it is not shown. Fischer's nomenclature has been avoided or replaced with simpler terms. The material balance approaches are called "methods" rather than "equations." The material balances are drawn to fit the circumstances. There is no need to formalize the method with a rigid set of equations.

In the derivations and calculations that follow, both VS (total volatile solids content of the sludge or decantate on dry solids basis) and FVSR are expressed throughout as fractions to avoid the frequent confusion that occurs when these terms are expressed as percentages. "Decantate" is used in place of the more commonly used "supernatant" to avoid the use of "s" in subscripts. Similarly, "bottoms" is used in place of "sludge" to avoid use of "s" in subscripts.

The "full mass balance" method

The "full mass balance" method must be used when steady conditions do not prevail over the time period chosen for the calculation. The chosen time period must be substantial, at least twice the nominal residence time in the digester (nominal residence time = average volume of sludge in the digester ÷ average volumetric flow rate. Note: when there is supernatant withdrawal, volume of sludge withdrawn should be used to calculate average volumetric flow rate). The reason for the long time period is to reduce the influence of short-term fluctuations in feed or product flow rates or compositions. If input compositions have been relatively constant for a long period of time, then the time period can be shortened.

An example where the full mass balance method would be needed is an aerobic digester operated as follows:

1. Started with the digester 1/4 full (Time zero).
2. Raw sludge is fed to the digester daily until digester is full.
3. Supernatant is periodically decanted and raw sludge is charged into the digester until not enough settling occurs to accommodate daily feeding. (Hopefully this will not occur until enough days have passed for adequate digestion.)
4. Draw down the digester to about 1/4 full (final time), discharging the sludge to sand beds.

The full mass balance is written as follows:

Sum of total volatile solids inputs in feed streams during the entire digestion period = sum of volatile solids outputs in withdrawals of decantate and bottoms + loss of volatile solids + accumulation of volatile solids in the digester. (1)

Loss of volatile solids is calculated from Equation 1. FVSR is calculated by Equation 2:

$$FVSR = \frac{\text{loss in volatile solids}}{\text{sum of volatile solids inputs}} \quad (2)$$

The accumulation of volatile solids in the digester is the final volume in the digester after the drawdowns times final volatile solids concentration less the initial volume at time zero times the initial volatile solids concentration.

To properly determine FVSR by the full mass balance method requires determination of all feed and withdrawal volumes, initial and final volumes in the digester and determination of volatile solids concentrations on all streams. In some cases, which will be discussed later, simplifications are possible.

The "approximate mass balance" method

If volumetric inputs and outputs are relatively constant on a daily basis, and there is no substantial accumulation of volatile solids in the digester over the time period of the test, an approximate mass balance (AMB) may be used. The basic relationship is stated simply:

volatile solids input rate = volatile solids output rate + loss of volatile solids. (3)

The FVSR is given by Equation 2.

No decantate, no grit accumulation - Calculation of FVSR is illustrated for Problem 1 in Table 1 which represents a simple situation with no decantate removal and no grit accumulation. An approximate mass balance is applied to the digester operated under constant flow conditions. Since no decantate is removed volumetric flow rate of sludge leaving the digester equals flow rate of sludge entering. Applying Equations 3 and 2,

$$FY_f = BY_b + \text{loss} \quad (4)$$

$$\text{Loss} = 100\ (50-30) = 2000 \quad (5)$$

$$FVSR = \frac{\text{Loss}}{FY_f} \quad (6)$$

$$FVSR = \frac{2000}{(100)(50)} = 0.40 \quad (7)$$

Nomenclature is given in Table 1. Note that the calculation did not require use of the fixed solids concentrations.

The calculation is so simple that one wonders why it is so seldom used. One possible reason is that the input and output volatile solids concentrations (Y_f and Y_b) may show greater coefficients of variation (standard deviation ÷ arithmetic average) than the fraction volatile solids (VS, fraction of the sludge solids that is volatile--note the difference between VS and Y).

Grit deposition - Grit deposition can be a serious problem in both aerobic and anaerobic digestion. The biological processes that occur in digestion dissolve or destroy the substances suspending the grit and it tends to settle. If agitation is inadequate to keep the grit particles in suspension they will accumulate in the digester. The approximate mass balance can be used to estimate accumulation of fixed solids.

For Problem 1, the balance yields the following:

$$FX_f = BX_b + \text{loss} \quad (8)$$

$$(100)(17) = (100)(17) + \text{Fixed Solids Loss} \quad (9)$$

$$\text{Fixed Solids Loss} = 0 \quad (10)$$

The material balance compares fixed solids in output with input. If some fixed solids are missing this loss term will be a positive number. Since we know that digestion does not consume fixed solids, we assume that the fixed solids are accumulating in the digester. As Equation 10 shows, the fixed solids loss equals zero. Note that for this case where input and output sludge flow rates are equal, the fixed solids concentrations are equal when there is no grit accumulation.

The calculation of fixed solids is repeated for Problem 2. Conditions in Problem 2 have been selected to show grit accumulation. Parameters are the same as in Problem 1 except for the fixed solids concentration (X_b) and parameters related to it. Fixed solids concentration in the digested sludge is lower than in Problem 1. Consequently, VS is higher and mass flow rate of solids (input rate = output rate + rate of loss of fixed solids) is presented in Equation 11-13.

$$FX_f = BX_b + \text{Fixed Solids Loss} \quad (11)$$

$$\text{Fixed Solids Loss} = FX_f - BX_b \quad (12)$$

$$\text{Fixed Solids Loss} = (100)(17) - (100)(15) = 200 \text{ kg/d} \quad (13)$$

The material balance, which only looks at inputs and outputs, informs us that 200 kg/d of fixed solids have not appeared in the outputs as expected. We know that fixed solids are not destroyed and conclude that they are accumulating in the bottom of the digester. The calculation of FVSR for Problem 2 is exactly the same as for Problem 1 (see Equations 4-7) and yields the same result. The accumulation of solids does not change the result.

Decantate withdrawal, no grit accumulation - In Problem 3, supernatant is withdrawn daily. Volatile and fixed solids concentrations are known for all streams but the volumetric flow rates are not known for decantate and bottoms. It is impossible to calculate FVSR without knowing the relative volume balance and a fixed solids balance, provided it can be assumed that loss of fixed solids (i.e., accumulation in the digester) is zero.

Selecting a basis for F of 100 m^3/d,

$$\text{Volume balance:} \quad 100 = B + D \tag{11}$$

$$\text{Fixed solids balance:} \quad 100\,X_f = BX_b + DX_d \tag{12}$$

Since the three Xs are known, B and D can be found.

Substituting 100-D for B and the values for the Xs from Problem 3 and solving for D and B.

$$(100)(17) = (100 - D)(23.50) + (D)(7.24) \tag{13}$$

$$D = 40.0\ m^3/d,\ B = 60.0\ m^3/d \tag{14}$$

The FVSR can now be calculated by drawing a volatile solids balance:

$$FY_f = BY_b + DY_d + \text{loss} \tag{15}$$

$$FVSR = \frac{\text{loss}}{FY_f} = \frac{FY_f - BY_b - DY_d}{FY_f} \tag{16}$$

$$FVSR = \frac{(100)(50) - (60)(41.42) - (40)(12.76)}{(100)(50)} = 0.40 \tag{17}$$

Unless information is available on actual volumes of decantate and sludge, there is no way to determine whether grit is accumulating in the digester. If it is accumulating, the calculated FVSR will be in error.

When we make the calculation shown in Equation 15-17, we assume that the volatile solids that are missing from the output streams are consumed by biological reactions that convert them to carbon dioxide and methane. We assume accumulation is negligible. Volatile solids are less likely to accumulate than fixed solids but it can happen. In poorly mixed digesters, the scum layer that collects at the surface is an accumulation of volatile solids. FVSR calculated by Equations 15-17 will be overestimated if volatile solids accumulation rate is substantial.

Decantate withdrawal and grit accumulation - In Problem 4, there is suspected grit accumulation. The quantity of B and D can no longer be calculated by Equations 11 and 12 because Equation 12 is no longer correct. The values of B and D must be measured. All parameters in Problem 4 are the same as Problem 3 except measured values for B and D are introduced into Problem 4. Values of B and D calculated assuming no grit accumulation (Problem 3--see previous section), and measured quantities are compared below:

	Calculated	Measured
B	60	49.57
D	40	50.43

The differences in the values of B and D are not large but they make a substantial change in the numerical value of FVSR. The FVSR for Problem 4 is calculated below:

$$FVSR = \frac{(100)(50) - (49.57)(41.42) - (50.43)(12.76)}{(100)(50)} = 0.461 \qquad (18)$$

If it had been assumed that there was no grit accumulation, FVSR would equal 0.40 (see Problem 3). It is possible to determine the amount of grit accumulation that has caused this change. A material balance on fixed solids is drawn:

$$FX_f = BX_b + DX_d + \text{Fixed Solids Loss} \qquad (19)$$

The fractional fixed solids loss due to grit accumulation is found by rearranging this equation:

$$\frac{\text{Fixed Solids Loss}}{FX_f} = \frac{FX_f - BX_6 - DX_d}{FX_f} \quad (20)$$

Substituting in the parameter values for Problem 4.

$$\frac{\text{Fixed Solids Loss}}{FX_f} = \frac{(100)(17) - (49.57)(23.50) - (50.43)(7.24)}{(100)(17)} \quad (21)$$

$$= 0.100$$

If this fixed solids loss of 10 percent had not been accounted for, the calculated FVSR would have been 13 percent lower than the correct value of 0.461. Note that if grit accumulation occurs and it is ignored, calculated FVSR will be lower than the actual value.

The Van Kleeck Equation

Van Kleeck first presented his equation without derivation in a footnote for a review paper on sludge treatment processing in 1945[4]. The equation is easily derived from total solids and volatile solids mass balances around the digestion system. Consider a digester operated under steady state conditions with decantate and bottom sludge removal. A total solids mass balance and a volatile solids mass balance are:

$$M_f = M_b + M_d + (\text{Loss of total solids}) \quad (22)$$

$$M_f \cdot VS_f = M_b \cdot VS_b + M_d \cdot VS_d + (\text{Loss of volatile solids}) \quad (23)$$

The masses must be mass of solids rather than total mass of liquid and solid because VS is an unusual type of concentration unit--it is "mass of volatile solids per unit mass of total solids."

It is now assumed that fixed solids are not destroyed and there is no grit deposition in the digester. The losses in Equations 22 and 23 then comprise only volatile solids so the losses are equal. It is also assumed that the VS of the decantate and of the bottoms are the same. This means that the bottoms may have a much higher solids content than the decantate but the

proportion of volatile solids to fixed solids is the same for both streams. Assuming then that VS_b equals VS_d and making this substitution in the defining equation for FVSR (Equation 2),

$$FVSR = \frac{\text{Loss of vol. solids}}{M_f \cdot VS_f} = 1 - \frac{(M_b + M_d)\, VS_b}{M_f \cdot VS_f} \tag{24}$$

From Equation 22, recalling that we have assumed that loss of total solids equals loss of volatile solids,

$$M_b + M_d = M_f - \text{loss of vol. solids} \tag{25}$$

Substituting for $M_b + M_d$ into Equation 24,

$$FRVS = 1 - \frac{(M_f - \text{Loss of vol. solids})}{M_f \cdot VS_f} \cdot VS_b \tag{26}$$

Simplifying further,

$$FRVS = 1 - \left(\frac{1}{VS_f} - FRVS\right) \cdot VS_b \tag{27}$$

Solving for FRVS,

$$FRVS = \frac{VS_f - VS_b}{VS_f - VS_f \cdot VS_b} \tag{28}$$

This is the form of the Van Kleeck Equation found in WPCF's Manual of Practice No. 16[3]. Van Kleeck[4] presented the equation in the following equivalent form:

$$FRVS = 1 - \frac{VS_b \cdot (1 - VS_f)}{VS_f \cdot (1 - VS_b)} \tag{29}$$

The Van Kleeck Equation is applied below to Problems 1-4 in Table 1 and compared to the approximate mass balance equation results:

	1	2	3	4
Approximate Mass Balance (AMB)	0.40	0.40	0.40	0.461
Van Kleeck (VK)	0.40	0.318	0.40	0.40

Problem 1: No decantate and no grit accumulation. Both methods give correct answers.

Problem 2: No decantate but grit accumulation. VK is invalid and incorrect.

Problem 3: Decantate but no grit accumulation. AMB method is valid VK method is valid only if $VS_b = VS_d$.

Problem 4: Decantate and grit acumulation. AMB method valid only if B and D are measured. VK method is invalid.

The Van Kleeck equation is seen to have serious shortcomings when applied to certain practical problems. The AMB method can be completely reliable whereas the Van Kleeck method is useless under some circumstances.

Review and Discussion of Calculation Methods and Results

Complete Mass Balance Method - The complete mass balance method allows calculation of volatile solids reduction of all approaches to digestion, even processes where final volumes in the digester does not equal initial volume and where daily flows are not steady. A serious drawback is the need for volatile solids concentration and volumes of all streams added to or withdrawn from the digester as well as initial and final volumes and concentrations in the digester. This can be a daunting task particularly for the small plants which are most likely to run their digesters in other than steady flow modes. For plants of this kind, an "equivalent" method that shows that the sludge has undergone the proper volatile solids reduction is likely to be a better choice than trying to demonstrate 38 percent volatile solids reduction. An aerobic sludge has received treatment equivalent to a 38 percent volatile solids reduction if specific oxygen uptake rate is below a specified maximum.

Anaerobically digested sludge has received treatment equivalent to a 38 percent volatile solids reduction if volatile solids reduction after batch digestion of the product sludge for 40 days is less than a specified maximum[5].

Approximate Mass Balance (AMB) Method - The approximate mass balance method assumes that daily flows are steady and reasonably uniform in composition, and that digester volume and composition does not vary substantially from day to day. Results of calculations and an appreciation of underlying assumptions show that the method is accurate for all cases, including withdrawal of decantate and deposition of grit, provided that in addition to composition of all streams the quantity of decantate and bottoms (the digested sludge) are known. If the quantities of decantate and bottoms are not known, the accumulation of grit cannot be determined. If accumulation of grit is substantial and FVSR is calculated assuming it to be negligible, FVSR will be lower than the true value. The result is conservative and could be used to show that minimum volatile solids reductons are being achieved.

The Van Kleeck Equation - The Van Kleeck Equation has underlying assumptions that should be made clear wherever the equation is presented. It is never valid when there is grit accumulation because it assumes the fixed solids input equals fixed solids output. Fortunately, it produces a conservative result in this case. Unlike the AMB method it does not provide a convenient way to check for accumulation of grit. It can be used when decantate is withdrawn provided VS_b equals VS_d. Just how big the difference between these VS values can be before an appreciable error in FVRS occurs is unknown, although it could be determined by making up a series of problems with increasing differences between the VS values, calculating FRVS using the AMB method and a Van Kleeck equation, and comparing results.

The shortcomings of the Van Kleeck equation are substantial and may eventually lead to a recommendation not to use it. However, it has one strong point. The VS of the various sludge and decantate streams are likely to show much lower coefficients of variation (standard deviation ÷ arithmetic average) than volatile solids and fixed solids concentration. Review of data are needed to determine how seriously the variation in concentrations affect the confidence interval of FVSR calculated by both methods. A hybrid approach may

turn out to be advantageous. The AMB method could be used first to determine if grit accumulation is occurring. If grit is not accumulating, the Van Kleeck equation could be used. If decantate is withdrawn, the Van Kleeck equation still cannot be used unless VS_b is nearly equal to VS_d.

Average Values - The concentrations and VS values used in the equations will all be averages. For the material balance methods, the averages should be weighted averages according to the mass of solids in the stream in question. The example below shows how to average the volatile solids concentration for four consecutive sludge additions.

Addition	Volume	Volatile Solids Concentration
1	10 m^3	50 kg/m^3
2	7 m^3	45 kg/m^3
3	15 m^3	40 kg/m^3
4	12 m^3	52 kg/m^3

$$Y_{av} = \frac{10 \times 50 + 7 \times 45 + 15 \times 40 + 12 \times 52}{10 + 7 + 15 + 12} = 46.3 \text{ kg/m}^3 \qquad (30)$$

For the Van Kleeck equation, the averages of VS are required. Properly they should be weighted averages based on the weight of the solids in each component of the average although an average weighted by the volume of the component or an arithmetic average may be sufficiently accurate if variation in VS is small. The following example demonstrates the calculation of all three averages.

Addition	Volume	Total Solids Concentration	VS
1	12 m^3	72 kg/m^3	0.75
2	8 m^3	50 kg/m^3	0.82
3	13 m^3	60 kg/m^3	0.80
4	10 m^3	55 kg/m^3	0.77

Weighted by Mass

$$VS\ av = \frac{12 \times 72 \times 0.75 + 8 \times 50 \times 0.82 + 13 \times 60 \times 0.80 + 10 \times 55 \times 0.77}{12 \times 72 + 8 \times 50 + 13 \times 60 + 10 \times 55} = 0.795 \quad (31)$$

Weighted by Volume

$$VS\ av = \frac{12 \times 0.75 + 8 \times 0.82 + 13 \times 0.80 + 10 \times 0.77}{12 + 8 + 13 + 10} = 0.783 \quad (32)$$

Arithmetic Average

$$VS\ av = \frac{0.75 + 0.82 + 0.80 + 0.77}{4} = 0.785 \quad (33)$$

In this example the arithmetic average was nearly as close as the volume-weighted average to the mass-weighted average, which is the correct value.

Decantate						
Volumetric flow rate	D	m^3/d	0	0		50.43
Volatile solids concentration	Y_d	kg/m^3	-	-	12.76	12.76
Fixed solids concentration	X_d	kg/m^3	-	-	7.24	7.24
Fraction volatile solids	VS_d	kg/kg	-	-	0.638	0.638
Mass flow rate of solids	M_d	kg/d	-	-		

1. Conditions are steady state; all daily flows are constant. Volatile solids are not accumulating in the digester, although grit may be settling out in the digester.

2. Numerical values are given at 3 or 4 significant figures. This is unrealistic considering the expected accuracy in measuring solids concentrations and sludge volumes. The purpose of extra significant figures is to allow more understandable comparisions to be made of the different calculation methods.

3. All volatile solids concentrations are based on the total solids, not merely on the suspended solids.

Foreword

The U.S. Environmental Protection Agency (EPA) is charged by Congress with protecting the Nation's land, air, and water resources. Under a mandate of national environmental laws, the Agency strives to formulate and implement actions leading to a compatible balance between human activities and the ability of natural systems to support and nurture life. To meet this mandate, EPA's research program is providing data and technical support for solving environmental problems today and building a science knowledge base necessary to manage our ecological resources wisely, understand how pollutants affect our health, and prevent or reduce environmental risks in the future.

The National Risk Management Research Laboratory (NRMRL) is the Agency's center for investigation of technological and management approaches for preventing and reducing risks from pollution that threaten human health and the environment. The focus of the Laboratory's research program is on methods and their cost-effectiveness for prevention and control of pollution to air, land, water, and subsurface resources; protection of water quality in public water systems; remediation of contaminated sites, sediments and ground water; prevention and control of indoor air pollution; and restoration of ecosystems. NRMRL collaborates with both public and private sector partners to foster technologies that reduce the cost of compliance and to anticipate emerging problems. NRMRL's research provides solutions to environmental problems by: developing and promoting technologies that protect and improve the environment; advancing scientific and engineering information to support regulatory and policy decisions; and providing the technical support and information transfer to ensure implementation of environmental regulations and strategies at the national, state, and community levels.

This publication has been produced as part of the Laboratory's strategic long-term research plan. It is published and made available by EPA's Office of Research and Development to assist the user community and to link researchers with their clients.

Acknowledgments

This guidance document was produced by the U.S. Environmental Protection Agency (EPA) Pathogen Equivalency Committee (PEC) whose members include Robert Bastian, Bob Brobst, John Cicmanec, G. Shay Fout, Hugh McKinnon, Mark Meckes, Frank Schaefer, Stephen Schaub, and James E. (Jim) Smith, Jr. The contributions of Jim Smith, who was instrumental in the administration, organization, and direction of this project; and of Bob Brobst, Mark Meckes, and Robert Bastian along with Greg B. Kester of the State of Wisconsin, who provided significant comments and guidance, are especially appreciated. Eliot Epstein and Nerissa Wu of E&A Environmental Consultants, Inc. in Canton, Massachusetts, prepared the document with information and comments from the PEC and from EPA and State sludge coordinators and private contributors including Joseph B. Farrell, a consultant, and Robert Reimers of Tulane University. The assistance of reviewers including John Colletti, Madolyn Dominy, Lauren Fondahl, Alia Roufaeal, and John Walker of EPA; Jeffrey G. Faust of Bio Gro; Joe Pearce of the State of North Carolina; Bob Southworth, a consultant; and all other contributors, too numerous to name, is very much appreciated.

The following individuals assisted by updating guidance for analytical procedures: Appendix F: Sample Preparation for Fecal Coliform Tests and *Salmonella* sp. Analysis - Mark Meckes; Appendix H: Method for the Recovery and Assay of Enteroviruses from Sewage Sludge - Shay Fout; Appendix I: Analytical Method for Viable Helminth Ova - Frank Schaefer; Appendix J: Composting: Basic Concepts Related to Pathogens and Vector Attraction - Eliot Epstein of E&A Environmental Consultants and Bob Brobst of EPA's Region 8 Office in Denver, CO.

Chapter 1
Introduction

1.1 What is Sewage Sludge?

Sewage sludge - the residue generated during treatment of domestic sewage (Figure 1-1) - is often used as an organic soil conditioner and partial fertilizer in the United States and many other countries. It is applied to agricultural land (pastures and cropland), disturbed areas (mined lands, construction sites, etc.), plant nurseries, forests, recreational areas (parks, golf courses, etc.), cemeteries, highway and airport runway medians, and home lawns and gardens (see photographs, pages 2 and 3). Certain treatment works (POTWs) own or have access to land dedicated solely to disposal of sewage sludge, a practice referred to as surface disposal. The U.S. Environmental Protection Agency (EPA), the primary federal agency responsible for sewage sludge management, encourages the beneficial use of sewage sludge through land application (Figure 1-2), after it has been appropriately treated for its intended use. In 1995 it was found that 54% of sewage sludge generated in the United States was land applied (Bastian, 1997).

Sewage sludge has beneficial plant nutrients and soil conditioning properties; however, it may also contain pathogenic bacteria, viruses, protozoa, parasites, and other microorganisms that can cause disease. Land application and surface disposal of untreated sewage sludge create a potential for human exposure to these organisms through direct and indirect contact. To protect public health from these organisms and from the pollutants that some sewage sludge contains, many countries now regulate the use and disposal of sewage sludge.

"Sewage Sludge" vs. "Biosolids"

Throughout the wastewater and sewage sludge industry, the term "sewage sludge" has largely been replaced by the term "biosolids." "Biosolids" specifically refers to sewage sludge that has undergone treatment and meets federal and state standards for beneficial use. The distinction between untreated sewage sludge and biosolids that have undergone processing and analysis will be made throughout this document.

What is Beneficial Use?

For the purposes of this document, land application is considered to be beneficial use. The document specifically deals with land application and the issues related to the pathogen and vector attraction reduction requirements for

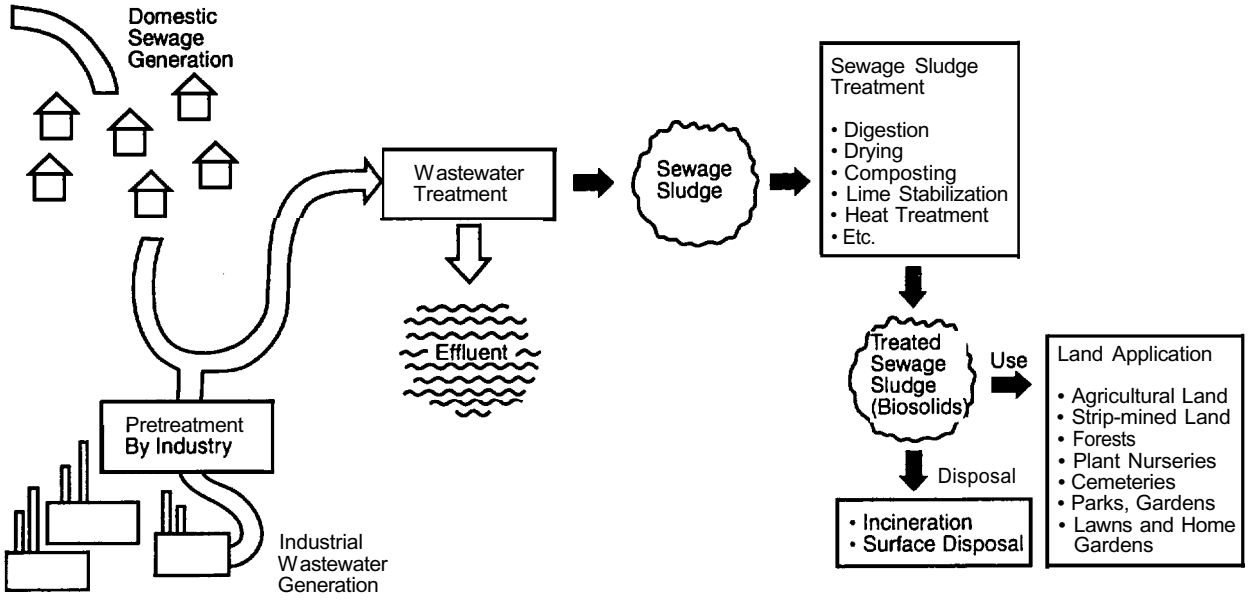

Figure 1-1. Generation, treatment, use, and disposal of sewage sludge.

The U.S. Environmental Protection Agency (EPA) will actively promote those municipal sludge management practices that provide for the beneficial use of sewage sludge while maintaining or improving environmental quality and protecting human health. To implement this policy, EPA will continue to issue regulations that protect public health and other environmental values. The Agency will require states to establish and maintain programs to ensure that local governments utilize sewage sludge management techniques that are consistent with federal and state regulations and guidelines. Local communities will remain responsible for choosing among alternative programs; for planning, constructing, and operating facilities to meet their needs; and for ensuring the continuing availability of adequate and acceptable disposal or use capacity.

land applied biosolids. For more information on the pathogen and vector attraction reduction requirements for the surface disposal of biosolids, please refer to Section 503.25 of the regulation.

1.2 U.S. Regulation of Treated Sewage Sludge (Biosolids)

In the United States, the use and disposal of treated sewage sludge (biosolids), including domestic septage, are regulated under 40 CFR Part 503[1] .This regulation, promulgated on February 19, 1993, was issued under the authority of the Clean Water Act (CWA) as amended in 1977 and the 1976 Resource Conservation and Recovery Act (RCRA). For most sewage sludge[2], the new regulation replaces 40 CFR 257, the original regulation governing the use and disposal of sewage sludge, which has been in effect since 1979.

The EPA policy shown below was developed in response to specific language in the CWA and RCRA federal policy statements in order to facilitate and encourage the beneficial reuse of sewage sludge (U.S. EPA, 1984).

Protection of Public Health and the Environment

Subpart D of the Part 503 regulation protects public health and the environment through requirements designed to reduce the potential for contact with the disease-bearing microorganisms (pathogens) in sewage sludge applied to the land or placed on a surface disposal site. These requirements are divided into:

- Requirements designed to control and reduce pathogens in treated sewage sludge (biosolids)
- Requirements designed to reduce the ability of the treated sewage sludge (biosolids) to attract vectors (insects and other living organisms that can transport biosolids pathogens away from the land application or surface disposal site)

Subpart D includes both performance and technology based requirements. It is designed to provide a more flexible approach than the approach in the Part 257, which required sewage sludge to be treated by specific listed or approved treatment technologies. Under Part 503, treatment works may continue to use the same processes they used under Part 257, but they now also have the freedom to modify conditions and combine processes with each other, as long as the applicable Part 503 requirements are met.

Environmental Effects of Pathogens in Sewage Sludge

Because of concern over the effect of pathogens from biosolids on animal health (certain human pathogens can cross species lines and infect animals, particularly warm blooded animals) the 503 regulations require that sewage sludge undergo pathogen treatment prior to land application. For sewage sludge subject to Class B pathogen treatment site restrictions are also required. While relatively little research has been conducted on specific inter-species crossover to wildlife, more information is available for grazing animals which are more likely to have a greater exposure to biosolids than wildlife. Available information on the impact of biosolids pathogens on grazing animals suggests that the Part 503 Subpart D requirements for pathogen control (which include restrictions on grazing) protect grazing animals (EPA, 1992). References regarding the impact of biosolids application on both wild and domestic animals are included at the end of this chapter.

1.3 Implementation Guidance

This document is not regulatory in nature. A complete copy of Subpart D of the Part 503 Regulation appears in Appendix B. This document is only intended to serve as a guide to pathogen and vector attraction reduction for anyone who is involved with the treatment of sewage sludge for land application. This includes:

- Owners and operators of domestic sewage treatment works
- Developers or marketers of sewage sludge treatment processes
- Groups that distribute and market biosolids products
- Individuals involved in applying biosolids to land
- Regional, state, and local government officials responsible for implementing and enforcing the Part 503 Subpart D regulation

[1] Because domestic septage is a form of sewage sludge, any use of the term "sewage sludge" in this document includes domestic septage.

[2] Sewage sludge generated at an industrial facility during the treatment of domestic sewage commingled with industrial wastewater in an industrial wastewater treatment facility is still covered under 40 CFR Part 257 if the sewage sludge is applied to the land.

- Consultants to these groups
- Anyone interested in understanding the federal requirements concerning pathogens in sewage sludge

This guide was previously released in 1993. The updates and amendments to this document are a product of comments and suggestions from the regulatory and sewage sludge management community. This edition of the document includes clarification of many of the sampling and monitoring issues and reflects the increased understanding of analytical issues. There are additional operational guidelines and examples of how a variety of facilities have complied with the Part 503 requirements. Some of the notable additions to this edition include:

- Clarification of Class A processes
- More specific guidelines for the operation of composting facilities
- More information on site restrictions including permit conditions which may apply to specific crops
- Recommendation for the use of the Kenner and Clark methodology for *Salmonella* sp. bacteria analysis
- Guidelines for retesting biosolids products that have been stored or remixed
- More information on public health and pathogens
- More information on sampling and monitoring protocols
- Updates on the Pathogen Equivalency Committee and approved processes

Other publications related to pathogen or vector attraction issues include the "Technical Support Document for Reduction of Pathogens and Vector Attraction in Sewage Sludge" (U.S. EPA, 1992) and "Part 503 Implementation Guidance" (U.S. EPA, 1995). Although the federal regulation under 40 CFR Part 503 includes restrictions for pollutant concentrations and application rates, this document is intended to clarify pathogen and vector related requirements and does not discuss pollutant limits.

This document does not discuss the general requirements and management practices which must be followed for land application of all biosolids except in the case of "exceptional quality" biosolids which have met certain pollutant limits and pathogen and vector attraction reduction requirements. In addition to meeting the regulation set forth in this document, bulk biosolids application must be conducted in accordance with agronomic rates, and biosolids appliers must ensure that applied biosolids are not applied within 10 meters of any water body, do not enter surface waters or wetlands without the approval of the appropriate permitting authority, and do not adversely affect endangered or threatened species or their habitats.

It should be noted that the Part 503 regulation and the sampling and monitoring requirements outlined in the regulation were developed as minimum requirements. EPA supports the beneficial use of treated sewage sludge (biosolids) and encourages facility operators and generators of biosolids products to develop sampling and monitoring plans that go beyond the minimum regulatory requirements as needed to ensure consistent product quality.

For most states, the authority for implementing the Part 503 regulation currently remains with the Regional EPA offices. A guide to EPA offices and relevant contacts can be found in Appendix A.

1.4 Definitions

The sections of this document that discuss specific regulatory requirements utilize the same terminology used throughout the Part 503 regulation in order to maintain consistency between the regulation and this guidance document. However, in some parts of this document, particularly in sections which discuss operational parameters and other issues related to biosolids management, terms which are not formally defined by the regulations are used. The following glossary has been provided in order to prevent confusion about the intent and jurisdiction of the Part 503 regulation.

Applier - The applier is the individual or party who land applies treated sewage sludge (biosolids). This may include farmers, municipalities, and private enterprises that land apply or their contractors.

Biosolids - Sewage sludge that has been treated and meets state and federal standards for land application.

Control - Some of the regulatory requirements make a distinction based on whether the biosolids preparer (see below) has "control" over the material. A preparer loses control over material when it is sold or given away. Until that point, the material is still within the control of the preparer even if the treatment process has ended and the material is in storage on or off-site.

Detectable Limits - Minimum concentration at which an analyte can be measured. The detectable limit for any given analyte varies depending on the lab methodology used and the volume of material analyzed. As such, detectable limits may fluctuate. Throughout this document, the term "detectable limit" refers to the limits as they are defined in the allowable lab methodologies outlined in the Appendices.

Exceptional Quality (EQ) Biosolids - The term "EQ" is not used in the Part 503 regulation, but it has become a useful description for regulators and biosolids preparers when referring to biosolids that meet the pollutant concentration limits of Table 3 of Section 503.13, Class A pathogen reduction, and one of the first eight treatment processes for meeting vector attraction reduction standards. Biosolids that fall into this category are not subject to the Part 503 general requirements and management practices for land application.

Preparer - The person(s) who generate biosolids from the treatment of domestic sewage in a treatment works or change the quality of the sewage sludge received from the generator. This includes facilities that derive a material from sewage sludge prior to land application of the material which could include wastewater treatment facilities, composting or other sewage sludge processing operations, and soil blenders who handle non-EQ biosolids materials. A soil blender who takes EQ biosolids and mixes them with other (non-sewage sludge) materials for land application is not a preparer. However, a soil blender that takes non-EQ biosolids and mixes it with other materials for land application is a preparer.

Product - This may include materials such as composted, heat-dried, lime stabilized, alkaline stabilized, or otherwise processed biosolids which have met the requirements of the Part 503. The term "product" is sometimes used in this document in discussions regarding material distribution. The term "sludge derived material" is used in the Part 503 to refer to these materials.

Sewage Sludge - The solid, semi-solid, or liquid residue generated during the treatment of municipal sewage in a treatment works. The term "biosolids" refers to sewage sludge which has undergone treatment and meets state and federal requirements for land application. The distinction between untreated sewage sludge and treated biosolids is made throughout this document.

1.5 Pathogen Equivalency Committee

The Pathogen Equivalency Committee (PEC) is made up of U.S. EPA experts who review pathogen and vector attraction reduction issues and make recommendations to the appropriate permitting authority. The primary role of the PEC is to review proposals for Processes to Significantly Reduce Pathogens (PSRP) and Processes to Further Reduce Pathogens (PFRP) equivalency determinations and to offer guidance on the issues associated with pathogen and vector attraction reduction.

More information on the PEC and the process of applying for equivalency is presented in Chapter 11.

1.6 What is in this Document?

Chapter 2 of this document provides basic information about pathogens and describes why pathogen control is required to protect public health and the environment, and Chapters 3 through 5 discuss the current federal requirements under Subpart D of Part 503. Chapters 6 and 7 review the different PFRP and PSRP processes, and Chapter 8 discusses vector attraction reduction issues. Chapters 9 and 10 summarize sampling and analysis protocols used to meet the quantitative requirements of Part 503. Chapter 11 outlines the process for applying for equivalency and discusses the kind of support EPA's Pathogen Equivalency Committee can provide to permitting authorities. Chapter 12 lists general references and additional resources related to biosolids use; specific references related to particular topics are also included at the end of each chapter.

The Appendices provide additional information on:

- Determination of volatile solids and residence time for digestion
- Sample preparation and analytical methods for meeting the Part 503 pathogen reduction requirements
- Tests for demonstrating vector attraction reduction
- Additional references on pathogen research and technical background to regulations

Appendix A lists EPA and state sewage sludge coordinators, and Appendix B contains Subpart D of the Part 503 regulation.

Chapter 2
Sewage Sludge Pathogens

2.1 What are Pathogens?

A pathogen is an organism or substance capable of causing disease. The Part 503 regulation only discusses pathogenic organisms, and throughout this document, "pathogen" refers only to living organisms, except where specified. Pathogens infect humans through several different pathways including ingestion, inhalation, and dermal contact. The infective dose, or the number of a pathogenic organism to which a human must be exposed to become infected, varies depending on the organism and on the health status of the exposed individual.

Pathogens that propagate in the enteric or urinary systems of humans and are discharged in feces or urine pose the greatest risk to public health with regard to the use and disposal of sewage sludge. Pathogens are also found in the urinary and enteric systems of other animals and may propagate in non-enteric settings. However, because this document is concerned with the regulation of sewage sludge, this chapter focuses on the pathogens most commonly found in the human enteric system.

2.2 Pathogens in Sewage Sludge

What pathogens can be found in sewage sludge?

The four major types of human pathogenic (disease-causing) organisms (bacteria, viruses, protozoa, and helminths) all may be present in domestic sewage. The actual species and quantity of pathogens present in the domestic sewage from a particular municipality (and the sewage sludge produced when treating the domestic sewage) depend on the health status of the local community and may vary substantially at different times. The level of pathogens present in treated sewage sludge (biosolids) also depends on the reductions achieved by the wastewater and sewage sludge treatment processes.

The pathogens in domestic sewage are primarily associated with insoluble solids. Primary wastewater treatment processes concentrate these solids into sewage sludge, so untreated or raw primary sewage sludges have higher quantities of pathogens than the incoming wastewater. Biological wastewater treatment processes such as lagoons, trickling filters, and activated sludge treatment may substantially reduce the number of pathogens in the wastewater (EPA, 1989). These processes may also reduce the number of pathogens in sewage sludge by creating adverse conditions for pathogen survival.

Nevertheless, the resulting biological sewage sludges may still contain sufficient levels of pathogens to pose a public health and environmental concern. Part 503 Regulation thus requires sewage sludge to be treated by a Class A pathogen treatment process or a Class B process with site restrictions. These requirements prevent disease transmission. Table 2-1 lists some principal pathogens of concern that may be present in wastewater and sewage sludge. These organisms and other pathogens can cause infection or disease if humans and animals are exposed to sufficient levels of the organisms or pathogens. The levels, called infectious doses, vary for each pathogen and each host.

As mentioned in Chapter 1, one concern is the potential effect of some human pathogens on animals. Enteric viruses can cross species lines, and animal life, particularly warm blooded animals, can be affected if they are exposed to some of the pathogens found in sewage sludge. Domestic animals are protected by site restrictions which limit grazing on sludge amended land.

How could exposure to these pathogens occur?

If improperly treated sewage sludge was illegally applied to land or placed on a surface disposal site, humans and animals could be exposed to pathogens directly by coming into contact with the sewage sludge, or indirectly by consuming drinking water or food contaminated by sewage sludge pathogens. Insects, birds, rodents, and even farm workers could contribute to these exposure routes by transporting sewage sludge and sewage sludge pathogens away from the site. Potential routes of exposure include:

Direct Contact

- Touching the sewage sludge.
- Walking through an area - such as a field, forest, or reclamation area - shortly after sewage sludge application.
- Handling soil from fields where sewage sludge has been applied.

Table 2-1. Principal Pathogens of Concern in Domestic Sewage and Sewage Sludge

Organism	Disease/Symptoms
Bacteria	
Salmonella sp.	Salmonellosis (food poisoning), typhoid fever
Shigella sp.	Bacillary dysentery
Yersinia sp.	Acute gastroenteritis (including diarrhea, abdominal pain)
Vibrio cholerae	Cholera
Campylobacter jejuni	Gastroenteritis
Escherichia coli (pathogenic strains)	Gastroenteritis
Enteric Viruses	
Hepatitis A virus	Infectious hepatitis
Norwalk and Norwalk-like viruses	Epidemic gastroenteritis with severe diarrhea
Rotaviruses	Acute gastroenteritis with severe diarrhea
Enteroviruses	
Polioviruses	Poliomyelitis
Coxsackieviruses	Meningitis, pneumonia, hepatitis, fever, cold-like symptoms, etc.
Echoviruses	Meningitis, paralysis, encephalitis, fever, cold-like symptoms, diarrhea, etc.
Reovirus	Respiratory infections, gastroenteritis
Astroviruses	Epidemic gastroenteritis
Caliciviruses	Epidemic gastroenteritis
Protozoa	
Cryptosporidium	Gastroenteritis
Entamoeba histolytica	Acute enteritis
Giardia lamblia	Giardiasis (including diarrhea, abdominal cramps, weight loss)
Balantidium co/i	Diarrhea and dysentery
Toxoplasma gondii	Toxoplasmosis
Helminth Worms	
Ascaris lumbricoides	Digestive and nutritional disturbances, abdominal pain, vomiting, restlessness
Ascaris suum	May produce symptoms such as coughing, chest pain, and fever
Trichuris trichiura	Abdominal pain, diarrhea, anemia, weight loss
Toxocara canis	Fever, abdominal discomfort, muscle aches, neurological symptoms
Taenia saginafa	Nervousness, insomnia, anorexia, abdominal pain, digestive disturbances
Taenia solium	Nervousness, insomnia, anorexia, abdominal pain, digestive disturbances
Necator americanus	Hookworm disease
Hymenolepis nana	Taeniasis

Source: Kowal (1985) and EPA (1989).

- Inhaling microbes that become airborne (via aerosols, dust, etc.) during sewage sludge spreading or by strong winds, plowing, or cultivating the soil after application.

Indirect Contact

- Consumption of pathogen-contaminated crops grown on sewage sludge-amended soil or of other food products that have been contaminated by contact with these crops or field workers, etc.
- Consumption of pathogen-contaminated milk or other food products from animals contaminated by grazing in pastures or fed crops grown on sewage sludge-amended fields.
- Ingestion of drinking water or recreational waters contaminated by runoff from nearby land application sites or by organisms from sewage sludge migrating into ground-water aquifers.
- Consumption of inadequately cooked or uncooked pathogen-contaminated fish from water contaminated by runoff from a nearby sewage sludge application site.
- Contact with sewage sludge or pathogens transported away from the land application or surface disposal site by rodents, insects, or other vectors, including grazing animals or pets.

The purpose of the Part 503 regulation is to place barriers in the pathway of exposure either by reducing the number of pathogens in the treated sewage sludge (biosolids) to below detectable limits, in the case.of Class A treatment, or, in the case of Class B treatment, by preventing direct or indirect contact with any pathogens possibly present in the biosolids.

Each potential pathway has been studied to determine how the potential for public health risk can be alleviated. The references listed at the end of this chapter include some of the technical writings which summarize the research on which the Part 503 regulation is based.

For example, the potential for public health impacts via inhalation of airborne pathogens was examined. Pathogens may become airborne via the spray of liquid biosolids from a splash plate or high-pressure hose, or in fine particulate dissemination as dewatered biosolids are applied or incorporated. While high-pressure spray applications may result in some aerosolization of pathogens, this type of equipment is generally used on large, remote sites such as forests, where the impact on the public is minimal. Fine particulates created by the application of dewatered biosolids or the incorporation of biosolids into soil may cause very localized fine particulate/dusty conditions, but particles in dewatered biosolids are too large to travel far, and the fine particulates do not spread beyond the immediate area. The activity of applying and incorporating biosolids may create dusty conditions. However, the biosolids are moist materials and do not add to the dusty conditions, and by the time biosolids have dried sufficiently to create fine particulates, the pathogens have been reduced (Yeager and Ward, 1981)

The study of each pathway and the potential for public health risk resulted in site restrictions that are protective of public health and the environment and that must be followed when Class B biosolids are land applied. While the site restrictions provided in the Part 503 rule are sufficient to protect the public from health impacts, workers exposed to Class B biosolids might benefit from several additional precautions. For example, dust masks should be worn for the spreading of dry materials, and workers should wash

their hands carefully after working with sewage sludge or biosolids. Other recommended practices for workers handling biosolids or sewage sludge include:

- Wash hands before eating, drinking, smoking or using the restroom.
- Use gloves when touching biosolids or sewage sludge or surfaces exposed to biosolids or sewage sludge.
- Remove excess sewage sludge or biosolids from shoes prior to entering an enclosed vehicle.
- Keep wounds covered with clean, dry bandages.
- If contact with biosolids or sewage sludge occurs, wash contact area thoroughly with soap and water.

Table 2-2 shows the various pathways of exposure and how the process requirements and site restrictions of the Part 503 regulation protect public health for each pathway.

Table 2-2. Pathways of Exposure and Applicable Site Restrictions (Class B Biosolids Only)

Pathways	Part 503 Required Site Restriction
Handling soil from fields where sewage sludge has been applied	No public access* to application sites until at least 1 year after Class B biosolids application.
Handling soil or food from home gardens where sewage sludge has been applied	Class B biosolids may not be applied on home gardens.
Inhaling dust**	No public access to application sites until at least 1 year after Class B biosolids application.
Walking through fields where sewage sludge has been applied*	No public access to fields until at least 1 year after Class B biosolids application.
Consumption of crops from fields on which sewage sludge has been applied	Site restrictions which prevent the harvesting of crops until environmental attenuation has taken place.
Consumption of milk or animal products from animals grazed on fields where sewage sludge has been applied	No animal grazing for 30 days after Class B biosolids have been applied.
Ingestion of water contaminated by runoff from fields where sewage sludge has been applied	Class B biosolids may not be applied within 10 meters of any waters in order to prevent runoff. from biosolids amended land from affecting surface water.
Ingestion of inadequately cooked fish from water contaminated by runoff from fields where sewage sludge has been applied	Class B biosolids may not be applied within 10 meters of any waters in order to prevent runoff from biosolids amended land from affecting surface water.
Contact with vectors which have been in contact with sewage sludge	All land applied biosolids must meet one of the Vector Attraction Reduction options (see Chapter 8).

*Public access restrictions do not apply to farm workers. If there is low probability of public exposure to an application site, the public access restrictions apply for only 30 days. However, application sites which are likely to be accessed by the public, such as ballfields, are subject to 1 year public access restrictions.

**Agricultural land is private property and not considered to have a high potential for public access. Nonetheless, public access restrictions still are applied.

2.3 General Information on Pathogens

The EPA has attempted, through this and other documents, to provide the public with a broad understanding of the risk assessment and scientific basis of the Part 503 regulation. The regulation is based on the results of extensive research and experience with land application of treated sewage sludge (biosolids). However, as for all regulations, proper interpretation and implementation of the regulation are the most important aspects of protecting public health and the environment.

Biosolids preparers should have a basic knowledge of microbiology so that they can:

- Understand the goals of the Part 503 regulation and what is expected to meet the requirements
- Address questions regarding pathogens and the protection of public health and the environment
- Design appropriate testing/sampling programs to meet the Part 503 requirements
- Make informed decisions about laboratory and analytical methodology selection

This section outlines some of the generic issues of pathogen testing and quantification. References related to these issues are listed at the end of this chapter as well as in Chapter 12. Other chapters discuss sampling and sample preservation as well as meeting the Part 503 requirements in more detail.

Survivability of Pathogens

Wastewater generally contains significantly high concentrations of pathogens which may enter the wastewater system from industries, hospitals, and infected individuals. The wastewater treatment process tends to remove pathogens from the treated wastewater, thereby concentrating the pathogens in the sewage sludge. Like any other living organisms, pathogens thrive only under certain conditions. Outside of these set conditions, survivability decreases. Each pathogen species has different tolerance to different conditions; pathogen reduction requirements are therefore based on the need to reduce all pathogenic populations. Some of the factors which influence the survival of pathogens include pH, temperature, competition from other microorganisms, sunlight, contact with host organisms, proper nutrients, and moisture level.

The various Class A and Class B pathogen reduction processes as well as the site restrictions for the land appli-

cation of Class B biosolids are based on research regarding the survivability of pathogens under specific treatment conditions. Table 2-3 shows a comparison of the survival of bacteria, viruses, and parasites in different sewage sludge treatments. Table 2-4 shows the survival time of various pathogens on soil or plant surfaces after land application of biosolids.

Identification of Pathogens

Some of the pathogens of concern that appear in domestic sewage and sewage sludge are shown in the photographs on pages 12 and 13. These include ascarids *(Ascaris lumbricoides* and *Toxacara),* whipworms *(Trichuris* sp.), tapeworms *(Hymenolepis* sp. and *Taenia* sp.), amoeba (*Entamoeba coli*), and giardia *(Giardia lamblia).* As shown in these photographs, several color staining procedures are needed to identify the organisms and the different structures within the organisms. The photograph of *Giardia lamblia* depicts specimens stained with Lugol's iodine solution, showing two nuclei, a median body, and axonemes in each. In addition, scientists use a blue filter when photographing the pathogenic organisms through a microscope. This filter is necessary to show the natural color of the organisms.

What Units are Used to Measure Pathogens?

Density of microorganisms in Part 503 is defined as number *of microorganisms per unit mass of total solids (dry weight).* Ordinarily, microorganism densities are determined as number per 100 milliliters of wastewater or sewage sludge. While the use of units of volume is sensible for wastewater, it is less sensible for sewage sludge. Many microorganisms in sewage sludge are associated with the solid phase. When sewage sludge is diluted, thickened, or filtered, the number of microorganisms per unit volume changes markedly, whereas the number per unit mass of solids remains almost constant. This argues for reporting their densities as the number present per unit mass of solids, which requires that sewage sludge solids content always be determined when measuring microorganism densities.

A second reason for reporting densities per unit mass of total solids is that biosolids application to the land is typically measured and controlled in units of mass of dry solids per unit area of land. If pathogen densities are measured as numbers per unit mass of total solids, the rate of pathogen application to the land is directly proportional to the mass of dry biosolids applied.

Table 2-3. Summary of the Effects of Sewage Sludge Treatment on Pathogens (Log Reductions Shown*)

PSRP Treatment	Bacteria	Viruses	Parasites (protozoa and helminths)
Anaerobic Digestion	0.5-4.0	0.5-2.0	0.5
Aerobic Digestion	0.5-4.0	0.5-2.0	0.5
Composting (PSRP)	2.0-4.0	2.0-4.0	2.0-4.0
Air Drying	0.5-4.0	0.5-4.0	0.5-4.0
Lime Stabilization	0.5-4.0	4.0	0.5

*A 1-log reduction (10-fold) is equal to a 90% reduction. Class B processes are based on a 2-log reduction.

Table 2-4. Survival Times of Pathogens in Soil and on Plant Surfaces[a]

	Soil		Plants	
Pathogen	Absolute Maximum[a]	Common Maximum	Absolute Maximum[b]	Common Maximum
Bacteria	1 year	2 months	6 months	1 month
Viruses	1 year[c]	3 months	2 months	1 month
Protozoan cysts[d]	10 days	2 days	5 days	2 days
Helminth ova	7 years	2 years	5 months	1 month

[a] For survival rates, see Sorber and Moore (1986).
[b] Absolute maximum survival times are possible under unusual conditions such as consistently low temperatures or highly sheltered conditions (e.g., helminth ova below the soil in fallow fields) (Kowal, 1985).
[c] Solisey and Shields, 1987.
[d] Little, if any, data are available on the survival times of Giardia cysts and Cryptosporidium oocysts.
Source: Kowal, 1985.

Different Methods for Counting Microorganisms

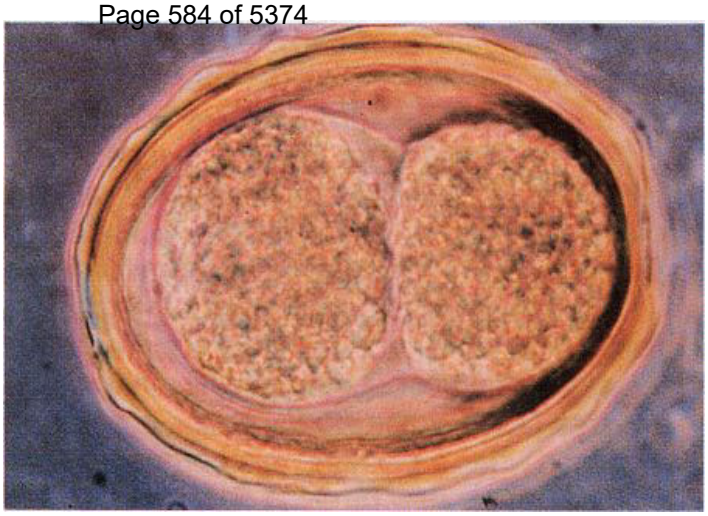
The methods and units used to count microorganisms vary depending on the type of microorganism. Viable helminth ova are observed and counted as individuals (numbers) under a microscope. Viruses are usually counted in plaque-forming units (PFU). Each PFU represents an infection zone where a single infectious virus has invaded and infected a layer of animal cells. For bacteria, the count is in colony-forming units (CFU) or most probable number (MPN). CFU is a count of colonies on an agar plate or filter disk. Because a colony might have originated from a clump of bacteria instead of an individual, the count is not necessarily a count of separate individuals. MPN is a statistical estimate of numbers in a sample. The sample is diluted at least once into tubes containing nutrient medium. The tubes are maintained under conditions favorable for bacterial growth. The original bacterial density in the sample is estimated based on the number of tubes that show growth and the level of dilution in those tubes.

Part 503 Density Limits

Under Part 503, the density limits for the pathogens are expressed as numbers of PFUs, CFUs, or MPNs per 4 grams dry weight sewage sludge. This terminology came about because most of the tests started with 100 ml of sewage sludge which typically contained 4 grams of sewage sludge solids. Also, expressing the limits on a "per gram" basis would have required the use of fractions (i.e., 0.25/g or 0.75/g). Density limits for fecal coliforms, the indicator organisms, however, are given on a "per gram" basis because these organisms are much more numerous than pathogens.

2.4 Protecting Public Health - The Part 503

The Part 503 regulation protects public health by limiting the potential for public exposure to pathogens. This is



Ascaris lumbricoides **(or var. suum) eggs, 66 µm, from anaerobically digested sludge. Two-cell stage.** (Photos on this page courtesy of Fox et al., 1981)

accomplished through treatment of the sewage sludge or through a combination of sewage sludge treatment and restrictions on the land application site that prevent exposure to the pathogens in the biosolids and allow time for the environment to reduce the pathogens to below detectable levels. The Part 503 vector attraction reduction requirements also help reduce the spread of pathogens by birds, insects, and other disease carriers (i.e. vectors) by requiring that all sewage sludge that is to be land applied undergo vector attraction reduction.

The Part 503 regulation also establishes the analytical protocol for pathogen analysis. More information on the quantification of pathogens and how pathogen reduction is measured is included in Chapter 10 and in the Appendices.

Reducing the Number of Pathogens

Pathogen reduction can be achieved by treating sewage sludge prior to use or disposal and through environmental attenuation. Many sewage sludge treatment processes are available that use a variety of approaches to reduce pathogens and alter the sewage sludge so that it becomes a less effective medium for microbial growth and vector attraction (Table 2-5). Processes vary significantly in their effectiveness. For example, some processes (e.g. lime stabilization) may effectively reduce bacteria and viruses but have little or no effect on helminth eggs. The effectiveness of a particular process can also vary depending on the conditions under which it is operated. For example, the length of time and the temperature to which sewage sludge is heated is critical to the effectiveness of heat-based treatment processes.

Part 503 lists sewage sludge treatment technologies that are judged to produce biosolids with pathogens sufficiently reduced to protect public health and the environment. The regulation also allows the use of any other technologies that produce biosolids with adequately reduced pathogens as demonstrated through microbiological monitoring. The Part 503 establishes two classifications of biosolids based on the level of pathogen reduction the biosolids have undergone. Class A biosolids are treated to the point at which pathogens are no longer detectable. For Class B biosolids, a combination of treatment and site restrictions are designed to protect public health and the environment.

Monitoring Indicator Species

Sewage sludge may contain numerous species of pathogenic organisms, and analyzing for each species is not practical. The microbiological requirements of the Part 503 are therefore based on the use of an indicator organism for the possible presence of pathological bacteria and both the representative and the hardiest of known species for viruses and helminths to represent the larger set of pathogenic organisms. The indicator and representative organ-

Table 2-5. General Approaches to Controlling Pathogens and Vector Attraction in Sewage Sludge

Approach	Effectiveness	Process Example [a]
Application of high temperatures (temperatures may be generated by chemical, biological, or physical processes).	Depends on time and temperature. Sufficient temperatures maintained for sufficiently long time periods can reduce bacteria, viruses, protozoan cysts, and helminth ova to below detectable levels. Helminth ova are the most resistant to high temperatures.	Composting (using biological processes to generate heat). Heat drying and heat treatment (use physical processes to generate heat, e.g., hot gases, heat exchangers). Pasteurization (physical heat, e.g., hot gases, heat exchangers). Aerobic digestion (biological heat)[b] Anaerobic digestion (physical heat)[b]
Application of radiation	Depends on dose. Sufficient doses can reduce bacteria, viruses, protozoan cysts, and helminth ova to below detectable levels. Viruses are most resistant to radiation.	Gamma and high-energy electron beam radiation.
Application of chemical disinfectants	Substantially reduces bacteria and viruses and vector attraction. Probably reduces protozoan cysts. Does not effectively reduce helminth ova unless combined with heat.	Lime stabilization
Reduction of the sewage sludge's volatile organic content (the microbial food source).	Reduces bacteria. Reduces vector attraction.	Aerobic digestion Anaerobic digestion Composting[b]
Removal of moisture from the sludge	Reduces viruses and bacteria. Reduces vector attraction as long as the sewage sludge remains dry. Probably effective in destroying protozoan cysts. Does not effectively reduce helminth ova unless combined with other processes such as high temperature.	Air or heat drying

[a] See Chapters 6 and 7 for a description of these processes. Many processes use more than one approach to reduce pathogens.
[b] Effectiveness depends on design and operating conditions.

isms are ones that have been found to respond to treatment processes and environmental conditions in a manner similar to other organisms. Monitoring the levels of these organisms, therefore, provides information about the survival of the larger group.

For example, for helminth ova, tests are employed to determine their presence and viability. The only helminth ova viability that can be determined is that of *Ascaris* sp. *Ascaris* is the hardiest of known helminths; thus, if conditions are such that it cannot survive, it is not possible for other helminth species *(Toxacara, Trichuris,* and *Hymenolepis)* to survive.

For viruses, a test is available that simultaneously monitors for several enterovirus species (a subset of enteric viruses - see Table 2-1), which are presumed to be good representatives for other types of enteric viruses.

Salmonella sp. are bacteria of great concern as well as good representatives of reduction of other bacterial pathogens because they are typically present in higher densities than are other bacterial pathogens and are at least as hardy.

Fecal coliforms are enteric bacteria that are used as indicators of the likelihood of the presence of bacterial pathogens. Although fecal coliforms themselves are usually not harmful to humans, their presence indicates the presence of fecal waste which may contain pathogens. These bacteria are commonly used as indicators of the potential presence of pathogens in sewage sludges. They are abundant in human feces and therefore are always present in untreated sewage sludges. They are easily and inexpensively measured, and their densities decline in about the same proportion as enteric bacterial pathogens when exposed to the adverse conditions of sludge processing (EPA, 1992).

In the case of Class B biosolids, the microbiological limit for meeting Alternative 1 is 2 million MPN fecal coliforms per gram dry weight. Because untreated sewage sludge generally contains up to 100 million MPN fecal coliforms per gram dry weight, this limit assumes an approximate 2-log reduction in the fecal coliform population. Studies of anaerobic or aerobic digestion of sludges have shown that the corresponding reduction in the pathogen population will be significant and sufficient so that environmental attenuation can reduce pathogen levels to below detection limit within the time period of site restrictions (Farrell et al.1985; Martin et al. 1990).

For some processes, fecal coliforms may be an overly conservative indicator. Because bacteria may proliferate outside of a host, reintroduction of fecal coliforms into treated biosolids may result in their growth. Concentrations may exceed the Class A fecal coliform limit even though pathogens are not present. In these cases, because fecal coliforms themselves are not a concern, testing directly for *Salmonella* sp. as an indicator of pathogen survival is permissible. Another issue with fecal coliforms is that the tests for these bacteria may overestimate the number of coliforms from human species. This is of particular concern when additives such as wood chips or other bulking agents have been added to biosolids (Meckes, 1995). In this case also, it is advisable to test directly for *Salmonella* sp.

It must however be noted that high counts of fecal coliforms may also indicate that a process is not being operated correctly. While a preparer may meet the regulatory requirements by testing for and meeting the regulatory limits for *Salmonella* sp., it is recommended that the pathogen reduction process be reviewed to determine at what point fecal coliforms are potentially not being reduced or are being reintroduced into treated biosolids, and ensure that process requirements are being fulfilled.

Regrowth of Bacteria

One of the primary concerns for biosolids preparers is regrowth of pathogenic bacteria. Some bacteria are unique among sewage sludge pathogens in their ability to multiply outside of a host. The processes outlined in the Part 503 regulation and in this document have been demonstrated to reduce pathogens, but even very small populations of certain bacteria can rapidly proliferate under the right conditions, for example, in sewage sludges in which the competitive bacterial populations have been essentially eliminated through treatment (see Section 4.3). Viruses, helminths, and protozoa cannot regrow outside their specific host organism(s). Once reduced by treatment, their populations do not increase. The Part 503 regulation contains specific requirements designed to ensure that regrowth of bacteria has not occurred prior to use or disposal.

Preventing Exposure

Exposure to pathogens in Class B biosolids is limited by restricting situations in which the public may inadvertently come into contact with biosolids and by limiting access to biosolids by vectors which may carry pathogens from the sewage sludge.

Site Restrictions

In the case of land application of Class B biosolids, site restrictions are sometimes required in order to protect public health and the environment. The potential pathways of exposure to Class B biosolids or to pathogens which may exist in Class B biosolids, are listed in Table 2.2 along with a description of how site restrictions impose barriers to exposure pathways. Site restrictions, discussed in detail in Chapter 5, place limits on crop harvesting, animal grazing, and public access on land where Class B biosolids have been applied.

The goal of site restrictions is to limit site activities such as harvesting and grazing until pathogens have been reduced by environmental conditions such as heat, sunlight, desiccation, and competition from other microorganisms. Table 2-3 summarizes the survival rates of four types of pathogenic organisms on soil and on plants. As shown,

helminths have the longest survival time; consequently, the duration of some of the site restrictions is based on helminth survival potential.

Vector Attraction Reduction

Insects, birds, rodents, and domestic animals may transport sewage sludge and pathogens from sewage sludge to humans. Vectors are attracted to sewage sludge as a food source, and the reduction of the attraction of vectors to sewage sludge to prevent the spread of pathogens is a focus of the Part 503 regulation. Vector attraction reduction can be accomplished in two ways: by treating the sewage sludge to the point at which vectors will no longer be attracted to the sewage sludge and by placing a barrier between the sewage sludge and vectors. The technological and management options for vector attraction reduction are discussed in Chapter 8.

2.5 Frequently Asked Questions

Because land application of biosolids has increased dramatically in the past several years, and because of some well publicized incidents of pathogen contamination (not necessarily related to biosolids), there have been many questions about the level to which public health is protected. Although it is not possible for every issue to be considered, the following section includes some of the questions which are most frequently asked. In addition, references are included at the end of this chapter and in Chapter 12.

Can biosolids carry the pathogen that causes mad cow disease?

It has been found that Bovine Spongiform Encephalopathy (BSE), or Mad Cow disease, is caused by a prion protein, or the resistant beta form of protein. The pathway for transmission is through the ingestion of tissue from infected animals. There has been no evidence that the BSE prion protein is shed in feces or urine. There have been no known cases of BSE in the United States, and the Food and Drug Administration (FDA) has taken various measures to prevent spread of the disease to or within the United States. For example, the primary route for infection, the use of animal carcasses in animal feed, is banned in this country. These measures have been effective, and BSE has not become a public health concern in the U.S. with regard to ingestion of beef or other exposure routes. Thus there should be no risk of BSE exposure from biosolids. (Tan, et al. 1999)

Is there any risk of HIV infection from biosolids?

The HIV virus is contracted through contact with blood or other body fluids of an infected individual. Feces and urine do not carry the HIV virus, but contaminated fluids may be discharged in minor amounts to the sewerage system. The conditions in the wastewater system are not favorable for the virus's survival. Separation from the host environment, dilution with water, chemicals from household and industrial sewer discharges, and the length of time from discharge to treatment all impede the survival of the virus (WEF/U.S. EPA Fact Sheet, 1997). HIV is seldom detected in wastewater, and the additional treatment that wastewater goes through, producing an effluent and sewage sludge which undergoes treatment to become Class A or B biosolids, makes it virtually impossible that biosolids would contain the HIV virus. (Lue-Hing, et al. 1999)

Wastewater treatment workers may come into contact with contaminated objects (bandages, condoms, etc.), but common sense hygiene practices already in place at wastewater treatment plants including the use of protective clothing and gloves greatly reduce the potential for exposure. The U.S. Department of Health and Human Services stated in 1990 that ". . .these workers (wastewater treatment workers) have no increased potential of becoming infected by blood borne infectious agents. Therefore, medical waste discarded to the sanitary sewer is not likely to present any additional public health effects to the wastewater workers or to the general public." (Johnson, et al. 1994)

What is a bioaerosol?

Bioaerosols are airborne water droplets containing microorganisms. These may include pathogenic microorganisms. Bioaerosols are a potential public health concern with regard to Class B biosolids because if pathogens are contained in the biosolids, they may become airborne and infect workers or the public through direct inhalation or through contact after settling on clothing or tools. It has been found that aerosolization of protozoa and helminths is unlikely, but bacteria or bacterial components (endotoxin) and viruses may become airborne and disperse from an application source depending on local meteorological and topographical conditions. However, Class B biosolids are rarely applied dry enough to become airborne; applying wet biosolids, particularly when the biosolids are incorporated or injected into the land, makes it highly unlikely that bioaerosols will be dispersed from land application.

The public access restrictions for land-applied Class B biosolids are based on the various pathways by which pathogens may impact public health. Site restrictions are adequate for the protection of public health, but site workers who are present during the application of Class B biosolids should follow standard hygiene precautions such as washing their hands after contacting biosolids and wearing dust masks if applying extremely dry material. More information on aerosolization of pathogens from land application can be found in the references following this chapter.

What is Aspergillus fumigatus?

Aspergillus fumigatus is a pathogenic fungus which is found in decaying organic matter such as sewage sludge, leaves, or wood. Because the fungus is heat resistant, and because sewage sludge composting facilities often use wood chips as a bulking agent, *A. fumigatus* has been associated with composting. Inhalation of *A. fumigatus* spores

may result in allergenic effects including irritation of the mucous membranes and asthma. However, *A. fumigatus* is a secondary, or opportunistic pathogen, and infection from *A. fumigatus* ("Aspergillosis") is limited to debilitated or immuno-compromised individuals. Studies of the health status of compost facility workers, the population most likely to be exposed to *Aspergillus fumigatus,* have not shown any negative health impacts (Millner, et al. 1994).

A. fumigatus is a ubiquitous fungus and has been found in homes, gardens, and offices at considerable levels. Numerous studies have been conducted to determine the level of the fungus in the areas surrounding active compost sites and compare this level to background concentrations of *Aspergillus fumigatus.* In general, it has been found that concentrations of *A. fumigatus* drop to background levels within 500-1000 feet of site activity. *A. fumigatus* is not covered in the Part 503.

There have been several incidents in which fruit has been contaminated with pathogens. Was this due to the land application of biosolids?

No. Pathogens such as *Salmonella* sp. and pathogenic strains of *E. coli* are typically associated with animal products (meat and eggs), but outbreaks have been known to occur as a result of vegetable or fruit contamination from the use of animal manures. Some of the well-publicized incidents include cases in which the consumption of fresh apple juice and cider resulted in widespread illness and the death of a child (Center for Disease Control, 1996). One case was found to be due to contamination from *E. coli* found in bovine feces, and the other was due to *Cryptosporidium* sp., also suspected to be from contact with animal manure. Other cases have involved the contamination of berries, melons, and alfalfa sprouts.

The Part 503 regulation applies only to the land application of biosolids. Education of field workers, regulation of working conditions, both domestically and abroad, and the use of animal manure products are beyond the scope of this document.

What is the Fate of Giardia and Cryptosporidium During Sewage Sludge Treatment?

Giardia lamblia and *Cryptosporidium parvurn* are protozoan parasites that can infect the digestive tract of humans and other warm blooded animals. Semi-aquatic mammals can serve as hosts, transmitting the disease to humans who consume contaminated water. Domestic mammals (particularly ruminants) can serve as infective hosts and contaminate a drinking water supply. It is currently believed that at least 7% of the diarrheal cases in the United States are caused by *Cryptosporidium* sp.

West (1991) notes that human protozoan parasites such as *Cryptosporidium* sp. and *Giardia* sp. possess several traits which facilitate waterborne transmission. They can (1) be excreted in feces in large numbers during illness; (2) persist through conventional sewage treatment; (3) survive in an environmentally robust form or demonstrate resilience to inactivation while in aquatic environments; (4) be resistant to commonly used disinfectants in the treatment of drinking water; and (5) require low numbers to elicit infection in susceptible hosts consuming or exposed to contaminated water.

Stadterman et al. (1995) reported on an anaerobic digestion study which spiked *Cryptosporidium* sp. oocysts into the digester and then periodically removed samples to determine the die-off. They found that conventional anaerobic digestion produces about a 2-log removal or a better log reduction on this protozoan than it does on bacteria and viruses, but it does not reduce densities to the low values needed for Class A for this pathogen. The reported survival of some protozoa after anaerobic digestion at 35°C is a cause for concern.

Jenkins et al. (1998) reported that ammonia inactivates these oocysts, depending on the concentration. High pH processes that increase the free ammonia concentration can inactivate these oocysts (although pH by itself does little).

A conservative conclusion from the limited research performed is that Class B processes can only be expected to reduce protozoan pathogens by about a factor of ten. The restrictions written into the regulation (access control, growing only certain crops, restrictions on root crops, etc.) are necessary to prevent exposure to these pathogens. The Class A processes reduce protozoa to below detectable limits.

Chapter 3
Overview of Part 503 Subpart D Requirements, Their Applicability, and Related Requirements

3.1 Introduction

The Subpart D (pathogen and vector attraction reduction) requirements of the 40 CFR Part 503 regulation apply to sewage sludge (both bulk sewage sludge and sewage sludge that is sold or given away in a bag or other container for application to the land) and domestic septage applied to the land or placed on a surface disposal site. The regulated community includes persons who generate or prepare sewage sludge for application to the land, as well as those who apply it to the land. Included is anyone who:

- Generates treated sewage sludge (biosolids) that is land applied or placed on a surface disposal site
- Derives a material from treated sewage sludge (biosolids)
- Applies biosolids to the land
- Owns or operates a surface disposal site

Sewage sludge cannot be applied to land or placed on a surface disposal site unless it has met, among other things, the two basic types of requirements in Subpart D:

- Requirements to ensure reduction of pathogens.
- Requirements to reduce the potential of the sewage sludge to attract vectors (rodents, birds, insects, and other organisms that can transport pathogens).

These two types of requirements are separated in Part 503 (they were combined in an earlier regulation, Part 257), which allows flexibility in how they are achieved. Compliance with the two types of requirements must be demonstrated separately. Therefore, demonstration that a requirement for reduced vector attraction has been met does not imply that a pathogen reduction requirement also has been met, and vice versa.

This chapter provides an overview of the Subpart D requirements, their applicability, and the requirements related to frequency of monitoring and recordkeeping. Where relevant, the titles of the sections in this chapter include the number of the Subpart D requirement discussed in the section. Chapters 4 through 8 provide detailed information on the pathogen and vector attraction reduction requirements.

Some of the pathogen and vector attraction reduction alternatives are suitable only for biosolids which have been processed by particular methods, such as by aerobic or anaerobic digestion or composting. Chapters 4 and 5 contain examples of how some facilities have met Part 503 requirements using appropriate pathogen and vector attraction reduction protocols, and Chapter 8 discusses each vector attraction option in detail.

3.2 Pathogen Reduction Requirements

Sewage Sludge [503.32(a) and (b)]

The pathogen reduction requirements for sewage sludge are divided into two categories: Class A and Class B. These requirements use a combination of technological and microbiological requirements to ensure reduction of pathogens.

The implicit goal of the Class A requirements is to reduce the pathogens in sewage sludge (including enteric viruses, pathogenic bacteria, and viable helminth ova) to below detectable levels, as defined in the 1992 regulation.

The implicit goal of the Class B requirements is to reduce pathogens in sewage sludge to levels that are unlikely to pose a threat to public health and the environment under the specific use conditions. For Class B biosolids that are applied to land, site use restrictions are imposed to minimize the potential for human or animal exposure to Class B biosolids for a period of time following land application and until environmental factors (e.g. sunlight, desiccation) have further reduced pathogens. Both Class A treatment of the sewage sludge which reduces pathogens to below detectable levels and the combination of Class B sewage sludge treatment and use restrictions on the land application site protect public health and the environment.

"Exceptional quality" (EQ) biosolids are biosolids which have met the Part 503 pollutant concentration limits (Table 3 of Section 503.13) as well as Class A pathogen reduction requirements and one of the first eight vector attraction reduction options listed in 503.33(b)(1) through (b)(8). EQ biosolids may be land applied without site restrictions.

Application of Class B biosolids must be conducted in compliance with site restrictions. Because it is not possible for regulators to follow the land application of biosolids applied on lawns and home gardens, Class B biosolids cannot be sold or given away in bags or other containers or applied on lawns and home gardens.

The testing requirements outlined throughout this document are minimum standards for compliance with the Part 503 rule. It should be pointed out that biosolids are properly distributed under the most recent test results. However, facilities which distribute biosolids between sampling events may wish to enhance their sampling programs to better ensure compliance with pathogen reduction requirements and to enhance public confidence in biosolids quality. More frequent testing should also enable the biosolids generators and preparers to better detect any changes in operations that might affect compliance and slow more rapid correction in any adverse changes. It should be noted that when additional determinations are made, even though they are in excess of Part 503 regulatory requirements, all these analytical results and records must be retained in the generator's, preparer's or land applier's files or reported to the regulatory authority depending on the classification of the operation or the regulatory authority's wishes.

Domestic Septage [503.32(c)]

As stated in Chapter 1, domestic septage is a form of sewage sludge. The requirements for domestic septage vary depending on how it is used or disposed. Domestic septage applied to a public contact site, lawn, or home garden must meet the same requirements as treated sewage sludge (biosolids) applied to these types of land (Class A requirements). Separate, less-complicated requirements for pathogen reduction apply to domestic septage applied to agricultural land, forests, or reclamation sites. These requirements include site restrictions to reduce the potential for human exposure to domestic septage and to allow for pH adjustment or environmental attenuation with site restrictions only on harvesting crops. No pathogen requirements apply if domestic septage is placed on a surface disposal site.

3.3 Vector Attraction Reduction (VAR) Requirements [503.33]

Subpart D provides 12 options to demonstrate vector attraction reduction. These are referred to in this document as Options 1 through 12. Table 8-2 summarizes these options, and Chapter 8 provides more detailed information on the options.

Reduction through Treatment

Options 1 through 8 apply to sewage sludge that has been treated in some way to reduce vector attraction (e.g., aerobic or anaerobic digestion, composting, alkali addition, drying). These options consist of either operating conditions or tests to demonstrate that vector attraction has been reduced in the treated sewage sludge. Option 12 is a requirement to demonstrate reduced vector attraction in domestic septage through elevated pH. This option applies only to domestic septage.

Reduction through Barriers

Options 9 through 11 are "barrier" methods. These options require the use of soil as a physical barrier (i.e., by injection, incorporation, or as cover) to prevent vectors from coming in contact with the land applied biosolids. They include injection of biosolids below the land surface, incorporation of biosolids into the soil, and placement of a cover over the biosolids. Options 9 through 11 apply to both biosolids and domestic septage. Option 11 may only be used at surface disposal sites.

Timing of Pathogen and Vector Attraction Reduction

In the case of Class A biosolids, pathogen reduction must take place before or at the same time as vector attraction reduction unless VAR Option 6, 7, or 8 is used. More information is provided in Section 4.2.

3.4 Applicability of the Requirements [503.15 and 503.25]

The applicability of the pathogen and vector attraction reduction requirements is covered in 503.15 and 503.25. Tables 3-1 to 3-3 summarize the applicability of the Subpart D requirements to sewage sludge and domestic septage.

Table 3-1. Subpart D Requirements for the Land Application of Bulk Biosolids[1]

	Applied to Agricultural Land, a Forest, a Public Contact Site[2], or a Reclamation Site[3]	Applied to a Lawn or Home Garden
Pathogen Requirements	Class A or Class B with site restrictions	Class A[4]
Vector Attraction Reduction Requirements	Options 1-10[5]	Options 1-8[5,6]

[1] Bulk biosolids are biosolids that are not sold or given away in a bag or other container for application to the land.
[2] Public contact site is land with a high potential for contact by the public, e.g., public parks, ball fields, cemeteries, plant nurseries, turf farms, and golf courses.
[3] Reclamation site is drastically distrubed land (e.g., strip mine, construction site) that is reclaimed using biosolids.
[4] The regulation does not permit use of biosolids meeting Class B requirements on lawns or home gardens, because it would not be feasible under these circumstances to impose the site restrictions that are an integral part of the Class B requirements.
[5] See Chapter 8 for a description of these options.
[6] The two vector attraction reduction requirements that cannot be met when bulk biosolids are applied to a lawn or a home garden are injection of the bulk biosolids below the land surface and incorporation of bulk biosolids into the soil. Implementation of these requirements for bulk biosolids applied to a lawn or a home garden would be difficult, if not impossible.

Table 3-2. Subpart D Requirements for Biosolids Sold or Given Away in a Bag or Other Container for Application to the Land

	Land Application
Pathogen Requirements	Class A[1]
Vector Attraction Reduction Requirements	Options 1-8[2]

[1]Class B biosolids cannot be sold or given away for use on home gardens or lawns because it is not feasible to impose the Class B site restrictions for these uses.
[2]Only the treatment-related options for vector attraction reduction apply to biosolids that are sold or given away in bags or other containers for application to the land, because of the barrier options, which are implemented at the site of application, would be impossible. See Chapter 8 for a description of these options.

Table 3-3. Subpart D Requirements for Domestic Septage Applied to Agricultural Land, a Forest, or a Reclamation Site[1] or Placed on a Surface Disposal Site

	Application to Agricultural Land, a Forest, or a Reclamation Site[2]	Surface Disposal
Pathogen Reduction Requirements	Class B site restrictions only or a pH adjustment (pH > 12 for 30 minutes) plus restrictions concerning crop harvesting	No pathogen requirements[3]
Vector Attraction Reduction Requirements	Options 9, 10, 12[4]	Options 9-12[4]

[1]For application to all other types of land, domestic septage must meet the same requirements as other forms of sewage sludge (see Tables 3-1 and 3-2).
[2]Reclamation site is drastically disturbed land (e.g., strip mine, construction site) that is reclaimed using biosolids.
[3]There is no pathogen requirement for domestic septage placed on a surface disposal site because site restrictions for grazing of animals, public access, and crop growing are already imposed by the Part 503, Subpart C management practices to reduce exposure to pollutants in domestic septage placed on a surface disposal site.
[4]See Chapter 8 for a description of these options.

Table 3-4. Frequency of Monitoring for Land Application and Surface Disposal

Amount of Biosolids[1] (metric tons dry solids per 365-day period)	Minimum Frequency
Greater than zero but less than 290[2]	Once per year
Equal to or greater than 290 but less than 1,500[2]	Once per quarter (four times per year)
Equal to or greater than 1,500 but less than 15,000[2]	Once per 60 days (six times per year)
Equal to or greater than 15,000[2]	Once per month (12 times per year)

[1]Either the amount of bulk biosolids applied to the land, or the amount of sewage sludge received by a person who prepares biosolids that are sold or given away in a bag or other container for application to the land (dry weight basis), or the amount of biosolids (excluding domestic septage) placed on a surface disposal site.
[2]290 metric tons = 320 tons (approximately 0.9 tons/day for a year).
1,500 metric tons = 1,653 tons (approximately 4.5 tons/day for a year).
15,000 metric tons = 16,534 tons (approximately 45 tons/day for a year).

3.5 Frequency of Monitoring

Sewage Sludge [503.16(a) and 503.26(a)]

The Class A and Class B pathogen requirements and the vector attraction reduction Options 1 through 8 (the treatment related methods) all involve some form of monitoring. The minimum frequency of monitoring for these requirements is given in Part 503.16(a) for land application and Part 503.26(a) for surface disposal. The frequency depends on the amount of biosolids used or disposed annually (see Table 3-4). The larger the amount used or disposed, the more frequently monitoring is required.

In addition to monitoring frequency, a sampling plan should address the minimum number of samples per sampling event that are necessary to adequately represent biosolids quality. Both of these issues are addressed in Chapter 9.

As stated throughout this document, the monitoring requirements set forth in the Part 503 and this document are the minimum requirements. Persons or facilities that generate and distribute biosolids are encouraged to go beyond the minimum required programs as necessary.

Domestic Septage [503.16(b) and 503.26(b)]

One of the requirements that can be used for demonstrating both pathogen reduction and vector attraction reduction in domestic septage is to elevate pH to 12 for 30 minutes (see Sections 5.6 and 8.13). When this requirement is to be met, each container of domestic septage (e.g., each tank truckload) applied to the land or placed on a surface disposal site must be monitored for pH over 30 minutes.

3.6 Sampling Stockpiled or Remixed Biosolids

In many cases there are several steps of preparation before biosolids are actually used or distributed. For example, some products such as composted biosolids may be prepared and then mixed with other materials to create a soil blend. Other biosolids products may be prepared and then stored either on site or at a field until the material can be applied. In some cases, resampling and/or re-establishment of the biosolids quality may be necessary. Whether or not biosolids must undergo additional sampling or processing depends on the classification of the biosolids and on whether the biosolids remain in the control of the preparer or if they have been distributed or sold.

EQ Biosolids

If the biosolids are classified as exceptional quality (EQ) (see Section 3.2), they may be distributed for land application without site restriction. EQ is an industry term rather than a regulatory term. Land application of EQ biosolids is not regulated by the Part 503 once the biosolids leave the control of the biosolids preparer. Therefore, soil blenders or other (non-preparer) users who take EQ biosolids may store the biosolids or mix the EQ biosolids with other (non-sewage sludge) materials without resampling the product.

Conversely, if EQ biosolids remain within the control of the preparer, they are still considered biosolids and are still covered by the Part 503. Like all Class A products, they must undergo microbiological testing at the last possible point before being distributed. In addition, if the preparer mixes the EQ biosolids or otherwise changes the quality of the biosolids, the new biosolids product must again comply with pathogen reduction, vector attraction reduction, and microbiological requirements.

Non-EQ Class A Biosolids

Class A biosolids are not necessarily classified as EQ biosolids; if pollutant levels exceed the Table 3 limits or if one of the first eight vector attraction options has not been met, the Class A biosolids are not considered EQ. All Class A biosolids must undergo microbiological testing just before they are distributed, so testing for fecal coliforms or *Salmonella* sp. must take place after storage. In addition, if the preparer mixes the Class A biosolids with other materials or otherwise changes the quality of the biosolids, the new biosolids product must comply with pathogen reduction, vector attraction reduction, and microbiological requirements.

Non-EQ Class A biosolids must also be monitored after they are distributed. For example, if a Class A compost which does not meet one of the EQ pollutant limits is sold to a vendor who mixes the compost with soil, the soil blender becomes a biosolids preparer, and must therefore comply with all Part 503 regulations. The new biosolids product must comply with pathogen reduction, vector attraction reduction, and microbiological requirements.

Class B Biosolids

Class B biosolids can meet pathogen reduction requirements at any point; there is no requirement that Class B biosolids be tested just before distribution. Therefore, biosolids which have met the Class B pathogen reduction requirements can be stored on site without retesting. However, if the Class B biosolids are mixed with other materials or the quality of the biosolids are otherwise altered, the new biosolids product must meet pathogen reduction and vector attraction reduction requirements.

The same is true for Class B biosolids that are distributed and no longer under the control of the preparer. Stored Class B biosolids do not have to be retested for pathogen reduction, unless the quality of the biosolids is somehow altered through mixing or further processing.

3.7 Recordkeeping Requirements [503.17 and 503.27]

Recordkeeping requirements are covered in Part 503.17 for land application and Part 503.27 for surface disposal. Records are required for both biosolids and domestic septage that are used or disposed. All records must be retained for 5 years except when the cumulative pollutant loading rates (CPLRs) in Subpart B (Land Application) of the Part 503 are used[1]. If CPLRs are used, records of pollutant loading at each site must be kept indefinitely. All records must be retained and made available to the regulatory authority upon request (see Section 3.8).

Land Application

Records must be kept to ensure that the biosolids meet the applicable pollutant limits, management practices[2], one of the pathogen requirements, one of the vector attraction reduction requirements and, where applicable, the site restrictions associated with land application of Class B biosolids. When biosolids are applied to land, the person preparing the biosolids for land application and the person applying bulk biosolids must keep records[3, 4]. The person applying biosolids that were sold or given away does not have to keep records.Table 3-5 summarizes the recordkeeping requirements for land application.

Surface Disposal

When biosolids are placed on a surface disposal site, the person preparing the biosolids and the owner/operator of the surface disposal site must keep records. In the case of domestic septage applied to agricultural land, forest, or a reclamation site or placed on a surface disposal site, the person applying the domestic septage and the owner/operator of the surface disposal site may be subject to pathogen record keeping requirements, depending on which vector attraction reduction option is met. Table 3-6 summarizes the pathogen-related recordkeeping requirements for surface disposal.

Certification Statement

In every case, recordkeeping involves signing a certification statement that the requirement has been met. Parts 503.17 and 503.27 of the regulation contain the required certification language.

3.8 Reporting Requirements for Sewage Sludge [503.18 and 503.28]

Reporting requirements for sewage sludge are found in Part 503.18 for land application and Part 503.28 for surface disposal. These requirements apply to Class I sludge management facilities[5] and to publicly owned treatment

[1]Cumulative pollutant loading rates are not related to pathogen control and therefore are not covered in this document.

[2]Pollutant limits and management practices are not related to the pathogen requirements and therefore are not covered in this document.

[3]Person as defined under Part 503.9 may be an individual, association, partnership, corporation, municipality, state or federal agency, or an agent or employee of a state or federal agency.

[4]When biosolids are prepared by one person, and another person who places it in a bag or other container for sale or give-away for application to the land changes the quality of that biosolids, both persons must keep the records required of preparers (see Table 3-5 and Section 3.6).

[5]A Class I sewage sludge management facility is any publicly owned treatment works (POTW) required to have an approved pretreatment program under 40 CFR 403.8(a) [including any POTW located in a state that has assumed local program responsibilities under 40 CFR 403.1 (e)] and any treatment works treating domestic sewage classified as a Class I sludge management facility by EPA or the state sludge management program because of the potential for its sewage sludge use or disposal practices to adversely affect public health and the environment.

works either with a design flow rate equal to or greater than 1 million gallons per day or that serve 10,000 or more people, or if specifically required by the permitting authority. Reports must be submitted to the regulatory authority (see Tables 3-5 and 3-6) and/or as the owner/operators of surface disposal sites (see Table 3-6) on February 19 of each year. There are no reporting requirements associated with the use or disposal of domestic septage, but records must be kept and made available to the regulatory authority upon request.

3.9 Permits and Direct Enforceability [503.3]

Permits

Under Part 503.3(a), the requirements in Part 503 may be implemented through (1) NPDES permits issued to treatment works treating domestic sewage by EPA permits issued by states with an EPA-approved sludge management program, and (2) by permits issued under Subtitle C of the Solid Waste Disposal Act; Part C of the Safe Drinking Water Act; the Marine Protection, Research, and Sanctuaries Act of 1972; or the Clean Air Act. Treatment works treating domestic sewage should submit a permit application[6] to the approved state program, or, if there is no such program, to the EPA Regional Sludge Coordinator (see Appendix A).

Direct Enforceability

Under Part 503.3(b), the requirements of Part 503 automatically apply and are directly enforceable even when no federal permit has been issued for the use or disposal of biosolids.

[6] See 40 CFR Parts 122/123, and 501; 54 FR 18716/May 2,1989; and 58 FR 9404/February 19, 1993, for regulations establishing permit requirements and procedures, as well as requirements for states wishing to implement approved sewage sludge management programs as either part of their NPDES programs or under separate authority.

Chapter 4
Class A Pathogen Requirements

4.1 Introduction

This chapter principally discusses the Class A pathogen requirements in Subpart D of the 40 CFR Part 503 regulation. Biosolids that are sold or given away in a bag or other container for application to land **must** meet these requirements (see Section 3.4). Bulk biosolids applied to a lawn or home garden also **must** meet these requirements. Bulk biosolids applied to other types of land **must** meet these requirements if site restrictions are not met (see Chapter 5 for guidance on Class B biosolids). Some discussion is, however, presented of vector attraction reduction.

There are six alternative methods for demonstrating Class A pathogen reduction. Two of these alternatives provide continuity with 40 CFR Part 257 by allowing use of Processes to Further Reduce Pathogens (PFRPs) and equivalent technologies (see Sections 4.8 and 4.9). Any one of these six alternatives may be met for the sewage sludge to be Class A with respect to pathogens. The implicit objective of all these requirements is to reduce pathogen densities to below detectable limits which are:

Salmonella sp.	less than 3 MPN per 4 grams total solids biosolids (dry weight basis)
Enteric viruses[1]	less than 1 PFU per 4 grams total solids biosolids (dry weight basis)
Viable helminth ova	less than 1 viable helminth ova/ 4 gram total solids biosolids (dry weight basis)

One of the vector attraction reduction requirements (see Chapter 8) also must be met when biosolids are applied to the land or placed on a surface disposal site. To meet the Part 503 regulatory requirements, pathogen reduction must be met before vector attraction reduction or at the same time vector attraction reduction is achieved.

For the following sections, the title of each section provides the number of the Subpart D requirement discussed in the section. The exact regulatory language can be found in Appendix B, which is a reproduction of Subpart D. Chapters 9 and 10 provide guidance on the sampling and analysis needed to meet the Class A microbiological monitoring requirements.

[1] Enteric viruses are monitored using a method that detects several enterovirus species--a subset of enteric viruses. This method is presumed to be a good indicator of enteric viruses. Since the objective of the Part 503 regulation is to reduce all enteric viruses to less than 1 PFU per 4 grams total solids sewage sludge, this document refers to "enteric viruses" when discussing this requirement, although, in reality, the detection method enumerates only enteroviruses.

4.2 Vector Attraction Reduction to Occur With or After Class A Pathogen Reduction [503.32(a)(2)]

Although vector attraction reduction and pathogen reduction are separate requirements, they are often related steps of a process. Chapter 8 discusses the vector attraction reduction options in greater detail.

The order of Class A pathogen reduction in relation to the reduction of vector attraction is important when certain vector attraction reduction options are used. Part 503.32(a)(2) requires that Class A pathogen reduction be accomplished before or at the same time as vector attraction reduction, except for vector attraction reduction by alkali addition [503.33(b)(6)] or drying [503.33(b)(7) and (8)] (see Chapter 8).

This requirement is necessary to prevent the growth of bacterial pathogens after sewage sludge is treated. Contamination of biosolids with a bacterial pathogen after one of the Class A pathogen reduction alternatives has been conducted may allow extensive bacterial growth unless: a) an inhibitory chemical is present, b) the biosolids are too dry to allow bacterial growth, c) little food remains for the microorganisms to consume, or d) an abundant population of non-pathogenic bacteria is present. Vegetative cells of non-pathogenic bacteria repress the growth of pathogenic bacteria by "competitive inhibition" which is in substantial part due to competition for nutrients. It should be noted that vector attraction reduction by alkali addition [503.3(b)(6)] or drying [503.3(b)(7)] and (8) is based on the characteristic of the biosolids (pH or total solids) remaining elevated. Should the pH drop or the biosolids absorb moisture, the biosolids may be more hospitable to microorganisms, and pathogenic bacteria, if introduced, may grow. Therefore it is recommended that biosolids treated with these methods be stored appropriately.

Biological treatment processes like anaerobic digestion, aerobic digestion, and composting produce changes in the

sewage sludge so that it satisfies one of the vector attraction reduction requirements [503.3(b)(1) through (5)]. They repress bacterial growth by minimizing the food supply and providing competition for the remaining food from non-pathogenic organisms. The pathogen reduction alternative must precede the vector attraction reduction process; otherwise, the large number of non-pathogenic bacterial cells would be killed and growth of pathogenic bacteria could occur. Certain pathogen reduction processes such as composting accomplish vector attraction reduction by a biological process simultaneously with thermal reduction of pathogens. A non-pathogenic bacterial community survives which adequately suppresses growth of pathogenic bacteria.

In the case of Class B biosolids, a population of non-pathogenic bacteria is retained and inhibits the growth of pathogenic bacteria through competition, and site restrictions are imposed with their land application to reduce the risk of exposure to pathogens. Therefore, bacterial growth is not a concern for Class B biosolids, and vector attraction reduction and pathogen reduction for compliance with the Part 503 Rule requirements may be met in any order.

4.3 Monitoring of Fecal Coliform or *Salmonella* sp. to Detect Growth of Bacterial Pathogens [503.32(a)(3)-(8)]

The goal of Class A processes is to reduce the level of pathogens to below detectable levels and below the level at which they are infectious. The Class A processes have been shown to sufficiently reduce pathogen levels in biosolids, and studies to date have not found that the growth of pathogenic bacteria may occur in materials after processes take place or during storage. Favorable conditions for the growth of pathogenic bacteria would be: adequate moisture, absence of an inhibitory chemical, and inadequate reduction of nutritive value of the sewage sludges.

Because Class A biosolids may be used without site restrictions, all Class A material must be tested to show that the microbiological requirements are met at the time when *it is ready to be used or disposed.* In addition to meeting process requirements, Class A biosolids must meet one of the following requirements:

- Either the density of fecal coliforms in the sewage sludge be less than 1,000 MPN[2] per gram total solids (dry weight basis).
- Or the density of *Sa/mone//a* sp. bacteria in the sewage be less than 3 MPN per 4 grams of total solids (dry weight basis).

Although the Part 503 regulation does not specify the number of samples that should be taken to show compliance with Class A density requirements, sampling programs should provide adequate representation of the biosolids generated. Chapter 9 provides guidance for calculating the number of samples that should be taken per sampling event. Unlike Class B biosolids, compliance with Class A requirements is not based on an average value. **Each sample analyzed must comply with the numerical requirements.**

The microbiological requirement must be met either:

- At the time of use or disposal[3], or
- At the time the biosolids are prepared for sale or give away in a bag or other container for land application, or
- At the time the biosolids or material derived from the biosolids is prepared to meet the requirements in 503.10(b), 503. 10(c), 503. 10(e), or 503. 10(f)[4].

If a facility stores material before it is distributed for use or disposal, microbiological testing should take place after storage.

In each case, the timing represents the last practical monitoring point before the biosolids are applied to the land or placed on a surface disposal site. Biosolids that are sold or given away cannot be monitored just prior to actual use or disposal; instead monitoring is required as it is prepared for sale or give away. Biosolids that meet the 503.10(b, c, d, or e) requirements are considered "Exceptional Quality" and are therefore not subject to further control (see Section 1.4). For this reason, the microbiological requirements must be met at the time the biosolids are prepared to meet the 503.10 requirements, which in most cases is the last time the biosolids are under the control of a biosolids preparer.

As discussed in Chapter 9, the timing of pathogen sampling is also a function of laboratory turnaround time. Obtaining results for fecal coliform and *Salmonella* sp. analysis may take several days if tests are performed in-house, but commercial labs may require more time to process and report results. It is not unusual for laboratories to have a turnaround time of 2 weeks, even for simple tests such as fecal coliform. If this is the case, this time should be factored into the sampling program so that results can be obtained before biosolids are distributed for use or disposal.

Monitoring Fecal Coliforms or Salmonella sp.

Fecal coliforms are used in the Part 503 as an indicator organism, meaning that they were selected to be monitored because reduction in fecal coliforms correlates to reduction in *Sa/mone//a* sp. and other organisms. The re-

[2]The membrane filter method is not allowed for Class A because, at the low fecal coliform densities expected, the filter would have too high a loading of sewage sludge solids to permit a reliable count of the number of fecal coliform colonies.

[3]Minus the time needed to test the biosolids and obtain the test results prior to use or disposal (see Chapter 10).

[4]The 503.10(b)(c)(e) and (f) requirements are not discussed in this document.

quirements were based on experimental work by Yanko (1987) and correlations developed from Yanko's data by Farrell (1993) which show that this level of fecal coliforms correlate with a very low level of *Salmonella* sp. detection in composted sewage sludge (EPA, 1992).

Anecdotal reports suggest that some composting facilities may have difficulty meeting this requirement even when *Salmonella* sp. are not detected. This might be expected under several circumstances. For example, very severe thermal treatment of sewage sludge during composting can totally eliminate *Salmonella* sp. yet leave residual fecal coliforms. If the sewage sludge has been poorly composted and thus is a good food source, fecal coliforms may grow after the compost cools down from thermophilic temperatures. Because the *Salmonella* sp. are absent, they cannot grow. An even more probable circumstance could occur if the sewage sludge is treated with lime before composting. Lime effectively destroys *Salmonella* sp. in sewage sludge and leaves surviving fecal coliforms (Farrell et al., 1974). Under conditions favorable for growth, the fecal coliforms can regrow to levels higher than 1,000 MPN per gram. Research has shown that detection of *Salmonella* sp. is much rarer in composted sewage sludge that has been lime treated and composted than detection of fecal coliforms. *Fecal coliform densities maybe high therefore compared to pathogen densities in such cases and maybe overly conservative.* For this reason, all of the Part 503 Class A alternatives allow the direct measurement of *Salmonella* sp. or fecal coliform analysis, but do not require both.

4.4 Alternative 1: Thermally Treated Sewage Sludge [503.32(a)(3)]

This alternative may be used when the pathogen reduction process uses specific time-temperature regimes to reduce pathogens. Under these circumstances, time-consuming and expensive tests for the presence of specific pathogens can be avoided. It is only necessary to demonstrate that:

- Either fecal coliform densities are below 1,000 MPN per gram of total solids (dry weight basis), or *Salmonella* sp. bacteria are below detection limits (3 MPN per 4 grams total solids [dry weight basis]) at the time the sewage sludge is used or disposed, at the time the sewage sludge is prepared for sale or given away in a bag or other container for land application, **or** at the time the sewage sludge or material derived from the sewage sludge is prepared to meet the requirements in 503.10(b), 503.10(c), 503.10(e), or 503.10(f).

- And the required time-temperature regimes are met.

Time-Temperature Requirement

Four different time-temperature regimes are given in Alternative 1. Each regime is based on the percent solids of the sewage sludge and on operating parameters of the treatment process. Experimental evidence (EPA, 1992) demonstrates that these four time-temperature regimes reduce the pathogenic organisms to below detectable levels.

The four time-temperature regimes are summarized in Table 4-1. They involve two different time-temperature equations. The equation used in Regimes A through C results in requirements that are more stringent than the requirement obtained using the equation in Regime D. For any given time, the temperature calculated for the Regime D equation will be 3 Celsius degrees (5.4 Fahrenheit degrees) lower than the temperature calculated for the Regimes A through C equation.

The time-temperature relationships described for Alternative 1 are based on extensive research conducted to correlate the reduction of various pathogens in sewage sludge to varying degrees of thermal treatment. The resulting time-temperature relationship which is the basis for Alternative 1 is shown in Figure 4-1. These requirements are similar to the FDA requirements for treatment of eggnog, a food product with flow characteristics similar to those of liquid sewage sludge. The Regimes A through D differ depending on the characteristics of sewage sludge treated and the type of process used because of the varying efficiency of heat transfer under different conditions.

It is important to note that **it is mandatory for all sewage sludge particles to meet the time-temperature regime.** Therefore, testing of temperatures throughout the sewage sludge mass and agitating the material to ensure uniformity would be appropriate. For processes such as thermophilic digestion, it is important that the digester design not allow for short circuiting of untreated sewage sludge. One approach that has been used to overcome this problem has been to draw off treated sewage sludge and charge feed intermittently with a sufficient time period between draw-down and feeding to meet the time-temperature requirement of Alternative 1. Another option would be to carry out the process in two or more vessels in series so as to prevent bypassing.

These time-temperature regimes are not intended to be used for composting (the time-temperature regime for composting is covered in Alternative 5: Processes to Further Reduce Pathogens).

A more conservative equation is required for sewage sludges with 7% or more solids (i.e., those covered by Regimes A and B) because these sewage sludges form an internal structure that inhibits the mixing that contributes to uniform distribution of temperature. The more stringent equation is also used in Regime C (even though this regime applies to sewage sludges with less than 7% solids) because insufficient information is available to apply the less stringent equation for times less than 30 minutes.

The time-temperature requirements apply to every particle of sewage sludge processed. Time at the desired temperature is readily determined for batch or plug flow operations, or even laminar flow in pipes. Time of contact also can be calculated for a number of completely mixed

Table 4-1. The Four Time-Temperature Regimes for Alternative 1 (Thermally Treated Sewage Sludge) [503.32(a)(3)]

Regime	Part 503 Section	Applies to	Required Time-Temperature[1]
A	503.32(a)(3)(ii)(A)	Sewage sludge with at least 7% solids (except those covered by Regime B)	$D = 131{,}700{,}000/10^{0.1400t}$ $t \geq 50°C$ (122°F)[2] $D \geq 0.0139$ (i.e., 20 minutes)[3]
B	503.32(a)(3)(ii)(B)	Sewage sludge with at least 7% solids that are small particles heated by contact with either warmed gases or an immiscible liquid[4]	$D = 131{,}700{,}000/10^{0.1400t}$ $t \geq 50°C$ (122°F)[2] $D \geq 1.74 \times 10^{-4}$ (i.e., 15 seconds)[5]
C	503.32(a)(3)(ii)(C)	Sewage sludge with less than 7% solids treated in processes with less than 30 minutes contact time	$D = 131{,}700{,}000/10^{0.1400t}$ 1.74×10^{-4} (i.e., 15 seconds) $\leq D \leq 0.021$ (i.e. 30 minutes)[6]
D	503.32(a)(3)(ii)(D)	Sewage sludge with less than 7% solids treated in processes with at least 30 minutes contact time	$D = 50{,}070{,}000/10^{0.1400t}$ $t \geq 50°C$ (122°F)[2] $D \geq 0.021$ (i.e. 30 minutes)[7]

[1]D = time in days; t = temperature (°C).
[2]The restriction to temperatures of at least 50°C (122°F) is imposed because information on the time-temperature relationship at lower temperatures is uncertain.
[3]A minimum time at 20 minutes is required to ensure that the sewage sludge has been uniformly heated.
[4]Two examples of sewage sludge to which this requirement applies are:
- Sewage sludge cake that is mixed with previously dried solids to make the entire mass a mixture of separate particles, and is then dried by contact with a hot gas stream in a rotary drier.
- Sewage sludge dried in a multiple-effect evaporator system in which the system sludge particles are suspended in a hot oil that is heated by indirect heat transfer with condensing steam.

[5]Time-at-temperature of as little as 15 seconds is allowed because, for this type of sewage sludge, heat transfer between particles and the healing fluid is excellent. Note that the temperature is the temperature achieved by the sewage sludge particles, not the temperature of the carrier medium.
[6]Time-at-temperature of as little as 15 seconds is allowed because heat transfer and uniformity of temperature is excellent in thiswage sludge. The maximum time of 30 minutes is specified because a less stringent regime (D) applies when time-at-temperature is 30 minutes or more.
[7]Time-at-temperature of at least 30 minutes is required because information on the effectiveness of this time-temperature regime for reducing pathogens at temperatures of less than 30 minutes is uncertain.

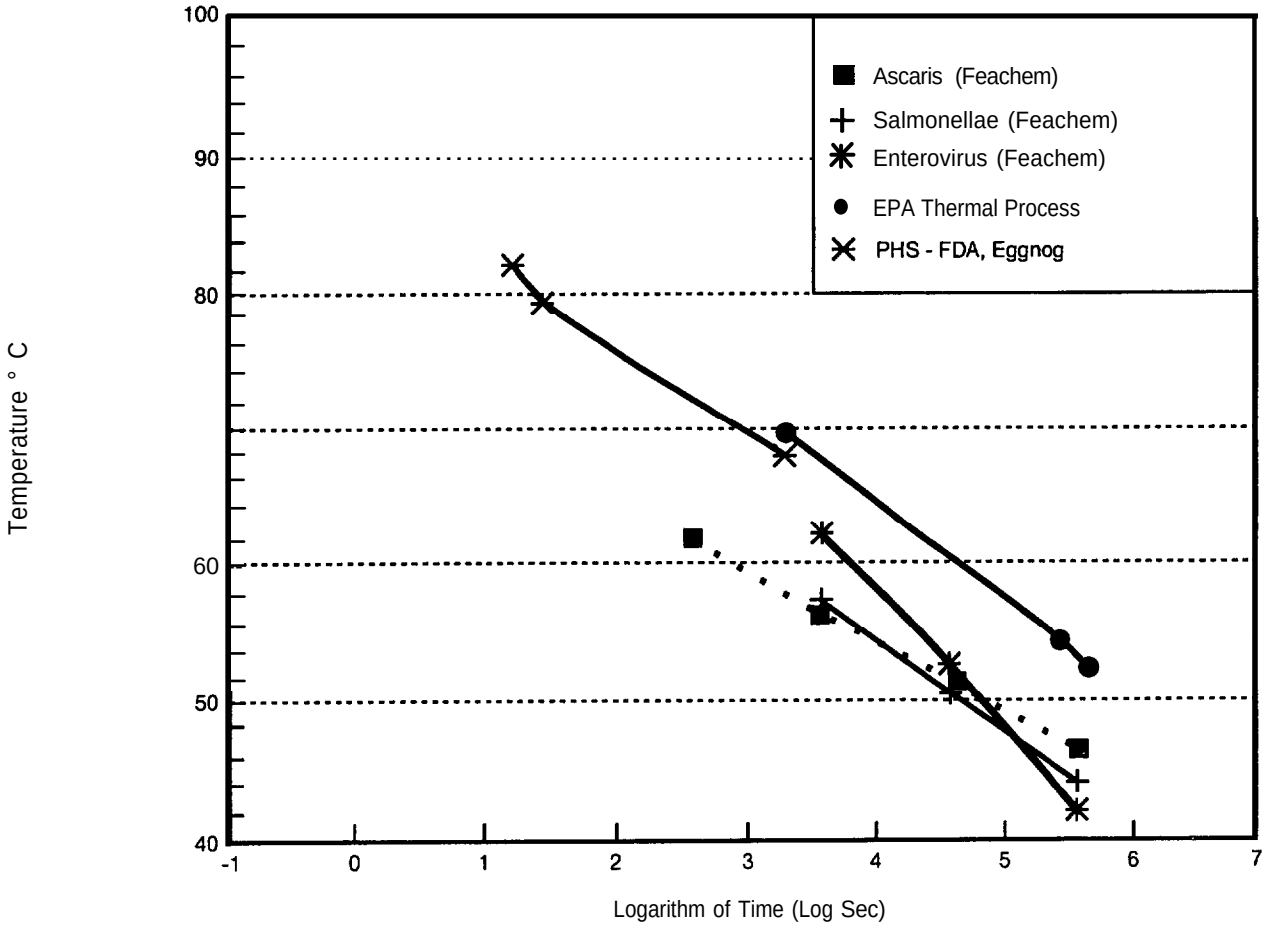

Figure 4-1. EPA's time-temperature relationship for thermal disinfection compared with other time-temperature relationships.

reactors in series (Schafer, et al, 1994). However, there are concerns that flow-through systems may permit some sludge to pass through without adequate treatment. It is recommended that facilities wishing to use this alternative for a flow-through system conduct tracer studies to demonstrate that sewage sludge is treated at the required temperature for sufficient time.

Vector Attraction Reduction

Thermally treated sewage sludge must be treated by an additional vector attraction reduction process since thermal treatment does not necessarily break down the volatile solids in sewage sludge. Vector attraction reduction can be met by further processing the sewage sludge with pH adjustment or heat drying (Options 6 and 7), or by meeting one of the other options (Options 8 – 11). Options 1 through 5 would not be applicable to thermally treated sludge unless the sludge was subject to biological digestion after or during thermal treatment.

Example of Meeting Class A Pathogen and Vector Attraction Reduction Requirements

Type of Facility	Thermophilic Anaerobic Digester Class A
	Digested sewage sludge is retained for at least 5 days at 50°C (Regime D). Sewage sludge is agitated regularly to ensure thorough mixing, and temperatures are monitored continually in a batch mode of operation.
Testing	Sewage sludge is sampled 6 times each year for pollutants and fecal coliforms. Compliance with vector attraction reduction is also monitored.
Vector Attraction Reduction	VAR is met by reducing volatile solids by over 38 percent. Five samples of input and output sewage sludge from each batch are analyzed for volatile solids content over a period of two weeks.
Use or Disposal	The Class A biosolids are land applied.

Microbiological Requirement

Microbiological monitoring for either fecal coliforms or *Salmonella* sp. is required to ensure that growth of bacterial pathogens has not occurred.

4.5 Alternative 2: Sewage Sludge Treated in a High pH-High Temperature Process (Alkaline Treatment) [503.32(a)(4)]

This alternative describes conditions of a high temperature-high pH process that has proven effective in reducing pathogens to below detectable levels. The process conditions required by the Part 503 regulation are:

- Elevating pH to greater than 12 and maintaining the pH for more than 72 hours.
- Maintaining the temperature above 52°C (126°F) throughout the sewage sludge for at least 12 hours during the period that the pH is greater than 12.
- Air drying to over 50% solids after the 72-hour period of elevated pH.

The hostile conditions of high pH, high temperature, and reduced moisture for prolonged time periods allow a variance to a less stringent time-temperature regime than for the thermal requirements under Alternative 1. The pH of the sewage sludge is measured at 25°C (77°F) or an appropriate correction is applied (see Section 10.7).

Example of Meeting Class A Pathogen and Vector Attraction Reduction

Type of Process Class	Alkaline Treatment
Pathogen Reduction	Alkaline material is used to bring sewage sludge pH to 12 for 72 hours during which time temperatures are above 52°C for 72 hours. Sewage sludge is agitated during the heat pulse phase to maintain even distribution, and temperature and pH are measured at multiple points within the sewage sludge. The sewage sludge is then moved to piles and maintained until moisture is reduced to 50 percent.
Testing	Piles are tested quarterly for pollutants and *Salmonella* sp. Samples are taken from stockpiled material, and material is not distributed for use or disposal until test results are received
Vector Attraction Reduction	VAR Option 6,pH adjustment; pH is to remain elevated until use/disposal.
Use or Disposal	During winter months (Nov-March), biosolids remain on site. In the spring, biosolids are re-tested for pathogens before being distributed.

Operational Issues

Because the elevated pH and temperature regimes must be met by the entire sewage sludge mass, operational protocols which include monitoring pH and temperature at various points in a batch and agitating the sewage sludge during operations to ensure consistent temperature and pH are appropriate.

Vector Attraction Reduction

The pH requirement of vector attraction reduction Option 6 is met when Alternative 2 is met. Compliance with Alternative 2 exceeds the pH requirements of Option 6.

Microbiological Requirements

As with all the Class A alternatives, microbiological monitoring for fecal coliforms or *Salmonella* sp. is required (see Section 4.3) to ensure that pathogens have been reduced and growth of pathogenic bacteria has not occurred.

4.6 Alternative 3: Sewage Sludge Treated in Other Processes [503.32(a)(5)]

This alternative applies to sewage sludge treated by processes that do not meet the process conditions required by Alternatives 1 and 2. This requirement relies on comprehensive monitoring of bacteria, enteric viruses and viable helminth ova to demonstrate adequate reduction of pathogens:

- Either the density of fecal coliforms in the sewage sludge must be less than 1000 MPN per gram of total solids (dry weight basis), or the *Salmonella* sp. bacteria in sewage sludge must be less than 3 MPN per 4 grams of total solids (dry weight basis) at the time the sewage is used or disposed, at the time the sewage sludge is prepared for sale or given away in a bag or other container for land application, or at the time the sewage sludge or material derived from the sewage sludge is prepared to meet the requirements in 503.10(b), 503.10(c), 503.10(e), or 503.10(f).
- The density of enteric viruses in the sewage sludge after pathogen treatment must be less than 1 PFU per 4 grams of total solids (dry weight basis).
- The density of viable helminth ova in the sewage sludge after pathogen treatment must be less than 1 per 4 grams of total solids (dry weight basis).

Testing for enteric viruses and viable helminth ova can be complicated by the fact that they are sometimes not present in the untreated sewage sludge. In this case, an absence of the organisms in the treated sewage sludge does not demonstrate that the process can reduce them to below detectable limits. For this reason, Alternative 3 requires that the feed sewage sludge be analyzed for enteric viruses and viable helminth ova. If these organisms are not detected in the feed sewage sludge, the sewage sludge is presumed to be acceptable as a Class A material until the next monitoring episode. Monitoring is continued until enteric viruses and/or viable helminth ova are detected in the feed sewage sludge (i.e., the density of enteric viruses is greater than or equal to 1 PFU per 4 grams total solids (dry weight basis) and/or the density of viable helminth ova is greater than or equal to 1 per 4 grams total solids (dry weight basis). At this point, the treated sewage sludge is analyzed to see if these organisms survived treatment. If enteric viruses densities are below detection limits, the sewage sludge meets Class A requirements for enteric viruses, and will continue to do so as long as the treatment process is operated under the same conditions that successfully reduced the enteric virus densities. If the viable helminth ova densities are below detection limits, the process meets the Class A requirements for enteric viruses and will continue to do so as long as the treatment process is operated under the same conditions that successfully reduced the viable helminth ova densities. Thus, it is essential to monitor and document operating conditions until adequate enteric virus and helminth ova reduction has been successfully demonstrated. Samples of untreated and treated sewage sludge must correspond (see Section 7.4).

Enteric Virus and Viable Helminth Ova Testing

Tests for enteric viruses and viable helminth ova take substantial time: 4 weeks to determine whether helminth ova are viable, and 2 weeks or longer for enteric viruses. The treatment works operator does not know whether the feed sewage sludge has enteric viruses or helminth ova until at least 2 to 4 weeks after the first samples for testing feed densities are taken. This works with rapid processes but long-term process systems need to have temporally related samples. In such cases, it may be feasible to obtain results within the processing time constraints. For enteric viruses, the sewage sludge should be stored frozen, unless the sample can be processed within 24 hours, in which case the samples may be stored at 4°C (39°F). For viable helminth ova, the sewage sludge should be stored at 4°C (39°F) (see Section 9.6).

Finding a laboratory that performs viable helminth ova and virus testing has been difficult for some sewage sludge preparers. Chapter 9 has more information on how to select a laboratory. State and Regional EPA sludge coordinators should also be contacted for information on qualified labs in the region.

Since this option relies on testing, rather than process and testing, to protect public health additional testings should be completed. At a minimum, a detailed sampling plan should be submitted to the permitting authority for review.

Vector Attraction Reduction

For both Alternatives 3 and 4, meeting vector attraction reduction depends on the process by which pathogen reduction is met. For example, sewage sludge subject to long-term storage may meet vector attraction reduction through volatile solids reduction (Options 1 – 3). Sewage sludges may also undergo additional processing or be applied following the requirements in Options 8 – 11.

Microbiological Requirements

As with all the Class A alternatives, microbiological monitoring for fecal coliforms or *Salmonella* sp. is required (see Section 4.3) to ensure that pathogens have been reduced and growth of pathogenic bacteria has not occurred.

4.7 Alternative 4: Sewage Sludge Treated in Unknown Processes [503.32(a)(6)]

The sewage sludge must meet the following limits at the time the biosolids (or material derived from sludge) are used or disposed, at the time the sewage sludge is prepared for sale or given away in a bag or other container for land application, or at the time the sewage sludge or material derived from the sewage sludge is prepared to meet the requirements in 503.10(b), 503.10(c), 503.10(e), or 503.10(f):

- The density of enteric viruses in the sewage sludge must be less than 1 PFU per 4 grams of total solids (dry weight basis).
- The density of viable helminth ova in the sewage sludge must be less than 1 per 4 grams of total solids (dry weight basis).

In addition, as for all Class A biosolids, the sewage sludge must meet fecal coliform or *Salmonella* sp. limits. As with Alternative 3, Alternative 4 depends on a successful sampling program that provides accurate representation of the sewage sludge's microbial quality (see Chapter 9).

Example Of Meeting Class A Pathogen Vector Attraction Reduction

Type of Facility	Unknown Process
Class	A
Pathogen Reduction	Sewage sludge is digested and retained in a lagoon up to 2 years. Sewage sludge is then moved to a stockpiling area where it may stay for up to 2 years.
Testing	Before sewage sludge is distributed, each pile, representing approximately 1 year of sewage sludge production, is tested for *Salmonella* sp., viable helminth ova, and enteric viruses. Since quarterly testing is mandated, based on the amount of sewage sludge which is used or disposed, four samples per pile are submitted
Vector Attraction Reduction	VAR is demonstrated by showing a 38 percent reduction in volatile solids. Records of incoming material and volume, bulk density, and percent volatile solids of outgoing material are used to calculate the reduction.
Distribution	Biosolids are distributed for land application and agricultural land.

Examples of situations where Alternative 4 may be used:

- Sewage sludge treatment process is unknown.
- The sewage sludge was produced with the process operating at conditions less stringent than the operating conditions at which the sewage sludge could qualify as Class A under other alternatives.

Enteric Virus and Viable Helminth Ova Testing

Tests for enteric viruses and viable helminth ova take substantial time: 4 weeks to determine whether helminth ova are viable, and 2 weeks or longer for enteric viruses. The treatment works operator does not know whether the feed sewage sludge has enteric viruses or helminth ova until at least 2 to 4 weeks after the first samples for testing feed densities are taken. This option works with rapid processes but long-term process systems need to have temporally related samples. In such cases, it may be feasible to obtain results within the processing time constraints. For enteric viruses, the sewage sludge should be stored frozen, unless the sample can be processed within 24 hours, in which case the samples may be stored at 4°C (39°F). For viable helminth ova, the sewage sludge should be stored at 4°C (39°F) (see Section 9.6).

Finding a laboratory that performs viable helminth ova and virus testing has been difficult for some sewage sludge preparers. Chapter 9 has more information on how to select a laboratory. State and Regional EPA sludge coordinators should also be contacted for information on qualified labs in the region.

Since this option relies on testing, rather than process and testing, to protect public health additional testings should be completed. At a minimum, a detailed sampling plan should be submitted to the permitting authority for review.

Vector Attraction Reduction

For both Alternatives 3 and 4, meeting vector attraction reduction depends on the process by which pathogen reduction is met. For example, sewage sludge subject to long-term storage may meet vector attraction reduction through volatile solids reduction (Options 1-3). Sewage sludges may also undergo additional processing or be applied following the requirement in Options 8-11.

4.8 Alternative 5: Use of PFRP [503.32(a)(7)]

Alternative 5 provides continuity with the 40 CFR Part 257 regulation. This alternative states that sewage sludge is considered to be Class A if:

- It has been treated in one of the Processes to Further Reduce Pathogens (PFRPs) listed in Appendix B of the regulation, and
- Either the density of fecal coliforms in the sewage sludge is less than 1,000 MPN per gram total solids (dry weight basis), or the density of *Salmonella* sp. bacteria in the sewage sludge is less than 3 MPN per 4 grams total solids (dry weight basis) at the time the sewage sludge is used or disposed, at the time the sewage sludge is prepared for sale or give away in a bag or other container for land application, or at the

time the sewage sludge or material derived from the sewage sludge is prepared to meet the requirements in 503.10(b), 503.10(c), 503.10(e), or 503.10(f).

To meet this requirement, the sewage sludge treatment processes must be operated according to the conditions listed in Appendix B of the regulation.

The Appendix B list of PFRPs is reproduced in Table 4-2. This list is very similar to the PFRP technologies listed in 40 CFR Part 257, with two major differences:

- All requirements related to vector attraction reduction have been removed.
- All the "add-on" processes listed in Part 257 are now full-fledged PFRPs.

Under this Alternative, treatment processes classified as PFRP under 40 CFR Part 257 can continue to be operated; however, microbiological monitoring must now be performed to ensure that the pathogen density levels are below detection limits and to ensure that growth of *Salmonella* sp. bacteria does not occur between treatment and use or disposal.

For all PFRP processes, the goal of temperature monitoring should be to represent all areas of a batch or pile and to ensure that temperature profiles from multiple points in the process all meet mandated temperatures. In some instances it may be possible to monitor representative areas of a batch or pile or a reasonable worst case area to ensure compliance. Chapter 7 contains more guidelines about the operation of PFRP processes.

4.9 Alternative 6: Use of a Process Equivalent to PFRP [503.32(a)(8)]

The 40 CFR Part 257 regulation allowed any treatment process to be determined *equivalent* to a PFRP. Under Alternative 6, sewage sludge is considered to be a Class A sewage sludge if:

- It is treated by any process equivalent to a PFRP, **and**
- Either the density of fecal coliforms in the sewage sludge is less than 1,000 MPN per gram total solids (dry weight basis), or the density of *Salmonella* sp. bacteria in the sewage sludge is less than 3 MPN per 4 grams total solids (dry weight basis) at the time the sewage sludge is used or disposed, at the time the sewage sludge is prepared for sale or give away in a bag or other container for land application, or at the time the sewage sludge or material derived from the sewage sludge is prepared to meet the requirements in 503.10(b), 503.10(c), 503.10(e), or 503.10(f).

Facilities that meet Alternative 6 for pathogen reduction must still meet vector attraction reduction requirements.

Processes Already Recommended as Equivalent

Processes recommended to be equivalent to PFRP are shown in Table 11.2. Products of all equivalent processes must still meet the Class A fecal coliform or *Salmonella* sp. requirements.

Who Determines Equivalency?

Part 503 gives the permitting authority responsibility for determining equivalency under Alternative 6. The EPA's Pathogen Equivalency Committee (PEC) is available as a resource to provide guidance and recommendations on equivalency determinations to both the permitting authority and the regulated community (see Chapter 11).

4.10 Frequency of Testing

The Part 503 regulation sets forth minimum sampling and monitoring requirements. Table 3-4 in Chapter 3 de-

Table 4-2. Processes to Further Reduce Pathogens (PFRPs) Listed in Appendix B of 40 CFR Part 503[1]

Composting	Using either the within-vessel composting method or the static aerated pile composting method, the temperature of sewage sludge is maintained at 55°C (131°F) or higher for 3 consecutive days. Using the windrow composting method, the temperature of the sewage sludge is maintained at 55°C (131°F) or higher for 15 consecutive days or longer. During the period when the compost is maintained at 55°C (131°F) or higher, there shall be a minimum of five turnings of the windrow.
Heat Drying	Sewage sludge is dried by direct or indirect contact with hot gases to reduce the moisture content of the sewage sludge to 10% or lower. Either the temperature of the sewage sludge particles exceeds 80°C (176°F) or the wet bulb temperature of the gas in contact with the sewage sludge as the sewage sludge leaves the dryer exceeds 80°C (176°F).
Heat Treatment	Liquid sewage sludge is heated to a temperature of 180°C (356°F) or higher for 30 minutes.
Thermophilic Aerobic Digestion	Liquid sewage sludge is agitated with air or oxygen to maintain aerobic conditions and the mean cell residence time (i.e., the solids retention time) of the sewage sludge is 10 days at 55°C (131°F) to 60°C (140°F).
Beta Ray Irradiation	Sewage sludge is irradiated with beta rays from an electron accelerator at dosages of at least 1.0 megarad at room temperature (ca. 20°C [68°F]).
Gamma Ray Irradiation	Sewage sludge is irradiated with gamma rays from certain isotopes, such as Cobalt 60 and Cesium 137, at dosages of at least 1.0 megarad at room temperature (ca. 20°C [68°F]).
Pasteurization	The temperature of the sewage sludge is maintained at 70°C (158°F) or higher for 30 minutes or longer.

[1]Chapter 7 provides a detailed description of these technologies.

scribes the minimum frequency at which the sewage sludge must be sampled and analyzed for pathogens or vector attraction reduction in order to meet regulatory requirements. In addition to meeting these minimal requirements, the EPA recommends that sewage sludge generators and preparers also consider the potential public health impact pathways and possible liability issues when designing a sampling program. In some cases, it may be appropriate to sample more frequently than the required minimum.

Classification of biosolids as Class A or Class B is based on the most recent test results available. For example, if a facility produces a Class A compost, and sampling is performed once each quarter, the compost produced after each test result verifying Class A is returned is also assumed to be Class A, assuming that the same process continues to be followed. If a test result indicates that compost is not achieving Class A, all compost subsequently generated would be classified as Class B (assuming it meets Class B requirements). The Class B classification would remain until a test result confirming Class A quality is returned.

This raises several issues. Land application of Class B biosolids without site restrictions is a violation of the 503 regulation. In addition, if material is mistakenly classified as EQ biosolids and land applied without restriction to the public, the biosolids preparer may be inadvertently creating a public health risk as well as opening the facility to liability. The key issues to consider are:

At what point between the two sampling events does the material change from Class A to C/ass B? This depends on the particular situation. The Class B test result may be an exception – the result of cross contamination or faulty sampling or monitoring for one pile. On the other hand, the test result could be indicative of an operation which is not adequately reducing pathogens. The piles which were actually sampled may have been used or distributed under the classification of the previous lab results while lab results were pending (it generally takes 2 weeks to get lab results back). Because distribution of this material as Class A would constitute a violation of the Part 503 regulation, it is recommended that material generated during and subsequent to a sampling event remain on site until lab results are available.

What can you do if you suspect Class B biosolids have been distributed as Class A biosolids? The first question to answer is: has this material created a public health risk. The material should be resampled to determine if it is indeed Class B and not Class A. The Part 503 requires that Class A biosolids meet either the fecal coliform or the *Salmonella* sp. requirements (except for Alternatives 3 and 4). If the material is out of compliance for fecal coliforms, it should immediately be tested for *Salmonella* sp. (and vice versa). In addition, the validity of the test results should be checked by contacting the lab and reviewing the data.

Material distribution should then be tracked to determine where material has been used. Businesses and individuals to whom material has been distributed should be notified and informed of the potential quality issue. If material is stockpiled at distribution points such as at a soil blender or landscaper, the material should be retested for pathogen levels, and distribution be curtailed until the process is reviewed and acceptable results are achieved. The facility may even consider recalling the biosolids from the users.

If material has already been distributed to public access areas, including homes, gardens, parks, or other public areas, the biosolids preparer may consider testing the soil. If the testing indicates problems, corrective actions may be necessary.

How can a situation like this be avoided? There are several sampling practices that a facility should follow in order to avoid a situation like this.

First, sampling should take place close enough to the time of distribution so that results accurately reflect material quality.

If possible, material sampled and subsequently produced material should not be distributed until the results are available; there is usually a 2-week waiting period for lab results for fecal coliform or *Salmonella* sp. analysis.

More frequent sampling can help pinpoint when operational conditions change. This may allow more rapid correction of operations.

Stockpile biosolids in discrete batches and take multiple samples per sampling event. This will allow better identification of which piles may be out of compliance and will allow for the distribution of material that is identified as Class A.

Chapter 5
Class B Pathogen Requirements and Requirements for Domestic Septage Applied to Agricultural Land, a Forest, or a Reclamation Site

5.1 Introduction

Class B pathogen requirements can be met in three different ways. The implicit objective of all three alternatives is to ensure that pathogenic bacteria and enteric viruses are reduced in density, as demonstrated by a fecal coliform density in the treated sewage sludge (biosolids) of 2 million MPN or CFU per gram total solids biosolids (dry weight basis)[1]. Viable helminth ova are not necessarily reduced in Class B biosolids.

Unlike Class A biosolids, which are essentially pathogen free, Class B biosolids may contain some pathogens. Site restrictions that restrict crop harvesting, animal grazing, and public access for a certain period of time are required. This allows environmental factors to further reduce pathogens. Where appropriate, these restrictions are designed to ensure sufficient reduction in viable helminth ova, one of the hardiest of pathogens, since these pathogens may not have been reduced during sewage sludge treatment.

The Class B requirements apply to bulk biosolids that are land applied to such areas as agricultural land, forests, public contact sites, or reclamation sites. Biosolids that are placed on a surface disposal site also must meet the Class B pathogen requirements, unless the active biosolids unit on which the biosolids are placed is covered at the end of each operating day (see Table 3-1). Because the use of Class B biosolids must be closely monitored, Class B biosolids cannot be given away or sold in bags or other containers.

Domestic septage applied to agricultural land, forest, or a reclamation site must meet all of the Class B site restrictions under 503.32(b)(5) unless the domestic septage has met specific pH requirements (see Section 5.6).

Class B biosolids and domestic septage also must meet one of the vector attraction reduction requirements (see Chapter 8). Note that the choice of vector attraction options may affect the duration of site restrictions in some cases. Specifically, if Option 9 or 10 (injection or incorporation) is used to reduce vector attraction, the restriction on harvesting for food crops grown below the soil surface (potatoes, carrots, etc.) is increased from 20 months to 38 months.

Sections 5.2 to 5.4 discuss the three alternative Class B pathogen requirements for sewage sludge. Section 5.5 discusses the site restrictions for land applied Class B biosolids, and Section 5.6 presents the requirements for domestic septage applied to agricultural land, forests, or reclamation sites. The title of each section provides the number of the Subpart D requirement discussed in the section. A copy of Subpart D can be found in Appendix B. Chapters 9 and 10 provide guidance on the sampling and analysis necessary to meet the Class B microbiological requirements.

5.2 Sewage Sludge Alternative 1: Monitoring of Fecal Coliform [503.32(b)(2)]

Alternative 1 requires that seven samples of treated sewage sludge (biosolids) be collected and that the geometric mean fecal coliform density of these samples be less than 2 million CFU or MPN per gram of biosolids (dry weight basis). This approach uses fecal coliform density as an indicator of the average density of bacterial and viral pathogens. Over the long term, fecal coliform density is expected to correlate with bacterial and viral pathogen density in biosolids treated by biological treatment processes (EPA, 1992).

Use of at least seven samples is expected to reduce the standard error to a reasonable value. The standard deviation can be a useful predictive tool. A relatively high standard deviation for the fecal coliform density indicates a wide range in the densities of the individual samples. This may be due to sampling variability or variability in the laboratory analysis, or it may indicate that the treatment process is not consistent in its reduction of pathogens. A high standard deviation can therefore alert the preparer that the sampling, analysis, and treatment processes should be reviewed.

[1]Farrell et al. (1985) have shown that if a processed sewage sludge is processed by aerobic or anaerobic digestion it has a fecal coliform density of 2 million MPN or CFU per gram, enteric viruses and bacteria are significantly reduced. A comparison of suspended solids densities in entering wastewater to suspended solids densities in treated sewage sludge shows that this density of fecal coliform in treated sewage sludge represents a 100-fold (Z-log) reduction in fecal coliform density, and is expected to correlate with an approximately 1.5 log (approximately 32-fold) reduction in *Salmonella* sp. density and an approximately 1.3 log (20-fold) reduction in the density of enteric viruses.

Each of the multiple samples taken for fecal coliform analysis should be taken at the same point in the process so that treatment of each sample has been equal. Samples must be handled correctly and analyzed within 24 hours in order to minimize the effect of the holding time of the sample on the microbial population.

Laboratory sampling should follow Standard Methods as outlined in the Appendix of this document. Standard QA/QC practices, including duplicates to verify laboratory protocols should be followed. Generally a log standard deviation between duplicate samples under 0.3 is acceptable for lab analyses.

Calculating the Geometric Mean for Class B Alternative 1

- Take seven samples over a 2-week period.
- Analyze samples for fecal coliform using the membrane filter or MPN dilution method.
- Take the log (Base 10) of each result.
- Take the average (arithmetic) of the logs.
- Take the anti-log of the arithmetic average. This is the geometric mean of the results.

Example: The results of analysis of seven samples of sewage sludge are shown below. The second column of the table shows the log of each result.

	Fecal Coliform (MPN/dry gram sewage sludge)	Log
Sample 1	6.4×10^6	6.81
Sample 2	4.8×10^4	4.68
Sample 3	6.0×10^5	5.78
Sample 4	5.7×10^5	5.76
Sample 5	5.8×10^5	5.76
Sample 6	4.4×10^6	6.64
Sample 7	6.2×10^7	7.80
Average (Arithmetic)		6.18
Antilog (geometric mean)		1.5×10^6
Log standard deviation		1.00*

Note that this sewage sludge would meet Class B fecal coliform requirements even though several of the analysis results exceed the 2.0×10^6/dry gram limit.
*Duplicate analyses on the same sample would give a much lower standard deviation. Variability is inflated by differences in feed and product over a 2-week sampling period.

Process parameters including retention time and temperature should be examined in order to verify that the process is running as specified. Monitoring equipment should be calibrated regularly.

The seven samples should be taken over a 2-week period in order to represent the performance of the facility under a range of conditions. For small facilities that are required to sample infrequently, sampling should be performed under worst case conditions, for example, during the winter when the climatic conditions are the most adverse.

It has been found that* for *Class B compliance, the MPN dilution method for fecal coliform analysis is more appropriate than the membrane filtration test. This is because colloidal and suspended solids may interfere with media transport through the membrane filter. Furthermore, concentration of toxic or inhibitory substances at the filter surface may affect results. It is therefore recommended that the membrane filter procedure be used *only after demonstrating comparability between the membrane filter test and the MPN method for a given sewage sludge.*

Example of Meeting Class B Pathogen Vector Attraction Reduction Requirements

Type of Facility	Extended Aeration
Class	B
Pathogen Reduction	----------
Testing	Quarterly testing for pollutants and for fecal coliform to determine if Class B Alternative 1 requirements are met.
Vector Attraction Reduction	The SOUR test is used to demonstrate compliance with VAR Option 4
Use or Disposal	The Class B biosolids are delivered to farmers along with information regarding analysis and site restrictions

5.3 Sewage Sludge Alternative 2: Use of a Process to Significantly Reduce Pathogens (PSRPs) [503.32(b)(3)]

The PSRP Class B alternative provides continuity with the 40 CFR Part 257 regulation. Under this Alternative, treated sewage sludge (biosolids) is considered to be Class B if it is treated in one of the "Processes to Significantly Reduce Pathogens" (PSRPs) listed in Appendix B of Part 503. The biological PSRP processes are sewage sludge treatment processes that have been demonstrated to result in a 2-log reduction in fecal coliform density. See Chapter 7.

The PSRPs in the Part 503 are reproduced in Table 5-1 and described in detail in Chapter 6. They are similar to the PSRPs listed in the Part 257 regulation, except that all conditions related to reduction of vector attraction have been removed. Under this alternative, sewage sludge treated by processes that are PSRPs under 40 CFR Part 257 are Class B with respect to pathogens. Unlike the comparable Class A requirement (see Section 4.8), this Class B alternative does not require microbiological monitoring.

However, monitoring of process requirements such as time, temperature, and pH is required.

Table 5-1. Processes to Significantly Reduce Pathogens (PSRPs) Listed in Appendix B of 40 CFR Part 503

1. Aerobic Digestion	Sewage sludge is agitated with air or oxygen to maintain aerobic conditions for a specific mean cell residence time (i.e., solids retention time) at a specific temperature. Values for the mean cell residence time and temperature shall be between 40 days at 20°C (68°F) and 60 days at 15°C (59°F).
2. Air Drying	Sewage sludge is dried on sand beds or on paved or unpaved basins. The sewage sludge dries for a minimum of 3 months. During 2 of the 3 months, the ambient average daily temperature is above 0°C (32°F).
3. Anaerobic Digestion	Sewage sludge is treated in the absence of air for a specific mean cell residence time (i.e., solids retention time) at a specific temperature. Values for the mean cell residence time and temperature shall be between 15 days at 35°C to 55°C (131°F) and 60 days at 20°C (68°F).
4. Composting	Using either the within-vessel, static aerated pile, or windrow composting methods, the temperature of the sewage sludge is raised to 40°C (104°F) or higher and remains at 40°C (104°F) or higher for 5 days. For 4 hours during the 5 day period, the temperature in the compost pile exceeds 55°C (131°F).
5. Lime Stabilization	Sufficient lime is added to the sewage sludge to raise the pH of the sewage sludge to 12 for ≥2 hours of contact.

5.4 Sewage Sludge Alternative 3: Use of Processes Equivalent to PSRP [503.32(b)(4)]

The Part 257 regulation allowed the sewage sludge to be treated by a process determined to be equivalent to a PSRP. Under Class B Alternative 3, sewage sludge treated by any process determined to be equivalent to a PSRP is considered to be Class B biosolids. A list of processes that have been recommended as equivalent to PSRP are shown in Table 11.1.

Part 503 gives the regulatory authority responsibility for determining equivalency. The Pathogen Equivalency Committee is available as a resource to provide guidance and recommendations on equivalency determinations to the regulatory authorities (see Chapter 11).

5.5 Site Restrictions for Land Application of Biosolids [503.32(b)(5)]

Potential exposure to pathogens in Class B biosolids via food crops is a function of three factors: first there must be pathogens in the biosolids; second, the application of Class B biosolids to food crops must transfer the pathogens to the harvested crop, and third, the crop must be ingested before it is processed to reduce the pathogens. Elimination of one of these steps eliminates the pathway by which public health may be affected. The use of Class A biosolids protects public health by reducing pathogens in sewage sludge to below detectable levels. Biosolids that meet the Class B requirements may contain reduced but still significant densities of pathogenic bacteria, viruses, protozoans, and viable helminth ova. Thus, site restrictions are to allow time for further reduction in the pathogen population. Harvest restrictions are imposed in order to reduce the possibility that food will be harvested and ingested before pathogens which may be present on the food have died off. Harvest restrictions vary, depending on the type of crop, because the amount of contact a crop will have with biosolids or pathogens in biosolids varies.

The site restrictions are primarily based in the survival rates of viable helminth ova, one of the hardiest of pathogens that may be present on sewage sludge. The survival of pathogens, including the helminth ova, depends on exposure to the environment. Some of the factors that affect pathogen survival include pH, temperature, moisture, cations, sunlight, presence of soil microflora, and organic material content. On the soil surface, helminth ova has been found to die off within 4 months, but survival is longer if pathogens are within the soil. Helminth ova have been found to survive in soil for several years (Smith, 1997; Kowal 1985). Site restrictions take this into account by making a distinction between biosolids that are applied to the land surface, biosolids that are incorporated into the soil after at least 4 months on the soil surface, and biosolids that are incorporated into the soil within 4 months of being applied.

Site restrictions also take the potential pathways of exposure into account. For example, crops that do not contact the soil, such as oat or wheat, may be exposed to biosolids, but pathogens on crop surfaces have been found to be reduced very quickly (30 days) due to exposure to sunlight, desiccation, and other environmental factors. Crops that touch the soil, such as melons or cucumbers, may also come into contact with biosolids particles, but pathogens in this scenario are also subject to the harsh effects of sunlight and rain and will die off quickly. Crops grown in soil such as potatoes are surrounded by biosolids amended soil, and pathogen die-off is much slower below the soil surface.

These pathways should be considered when determining which site restriction is appropriate for a given situation. The actual farming and harvesting practices as well as the intended use of the food crop should also be considered. For example, oranges are generally considered a food crop that does not touch the ground. However, some oranges grow very low to the ground and may come into contact with soil. If the oranges that have fallen to the ground or grew touching the ground are harvested for direct consumption without processing, the 14-month harvest restriction for crops that touch the soil should be followed. Orange crops which do not touch the ground at all would not fall under the 14-month harvest restriction; harvest would be restricted for 30 days under 503.32(b)(5)(iv)

which covers food crops that do not have harvested parts in contact with the soil. For similar situations, the potential for public health impacts must be considered. Harvest practices such as the use of fallen fruit or washing or processing crops should be written into permits so that restrictions and limits are completely clear. Figure 5-1 illustrates the steps of exposure that should be considered when making a decision about harvest and site restrictions. In addition, several examples of permit conditions are included. The site restrictions for land applied Class B biosolids are summarized below. The regulatory language is given in italics. Note that the restrictions apply only to the harvesting of food crops, but not to the planting or cultivation of crops.

Food Crops with Harvested Parts That Touch the Sewage Sludge/Soil Mixture

503.32(b)(5)(i): Food crops with harvested parts that touch the sewage sludge/soil mixture and are totally above the land surface shall not be harvested for 14 months after application of sewage sludge.

This time frame is sufficient to enable environmental conditions such as sunlight, temperature, and desiccation to further reduce pathogens on the land surface. Note that the restriction applies only to harvesting. Food crops can be planted at any time before or after biosolids application, as long as they are not harvested within 14 months

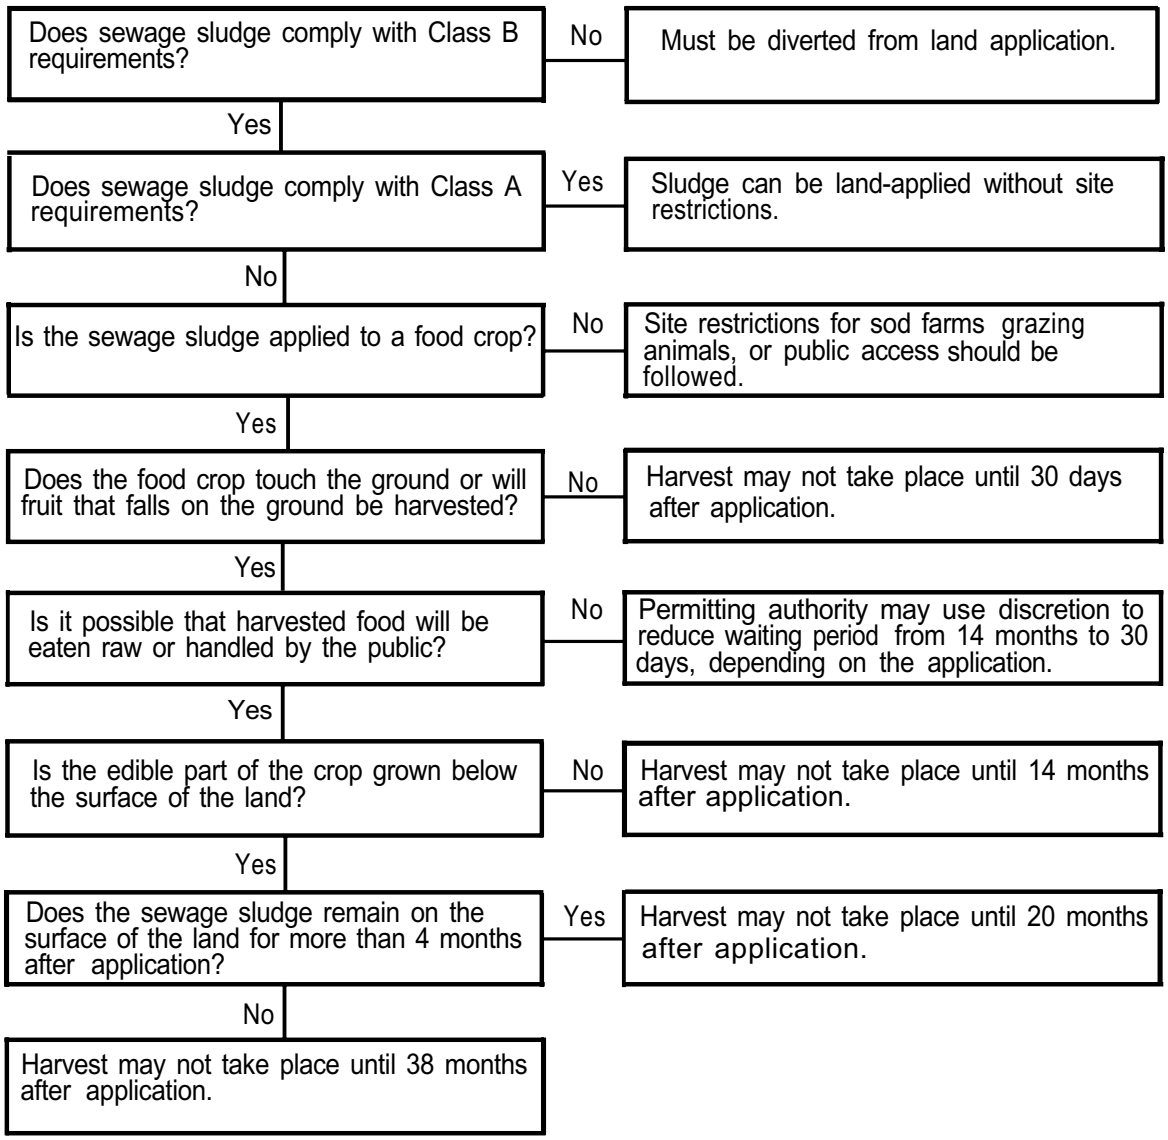

Figure 5-1. Decision tree for harvesting and site restrictions.

after sludge application. Examples of food crops grown on or above the soil surface with harvested parts that typically touch the sewage sludge/soil mixture include lettuce, cabbage, melons, strawberries, and herbs. Land application should be scheduled so that crop harvests are not lost due to harvest restrictions.

Food Crops with *Harvested Parts Below the Land Surface*

503.32(b)(5)(ii): Food crops with harvested parts below the surface of the land shall not be harvested for 20 months after application of sewage sludge when the sewage sludge remains on the land surface for 4 months or longer prior to incorporation into the soil.

Pathogens on the soil surface will be exposed to environmental stresses which greatly reduce their populations. Helminth ova have been found to die off after 4 months on the soil surface (Kowal, 1994). Therefore, a distinction is made between biosolids left on the soil surface for 4 months and biosolids which are disced or plowed into soil more quickly.

For a September 1999 harvest, biosolids could be applied to the soil surface up to the end of December 1997, plowed or disced into the soil in April 1998, and the crop planted in order to allow it to be harvested in September 1999. Examples of crops with harvested parts below the land surface are potatoes, radishes, beets, onions and carrots.

Examples of Site Restrictions for Questionable Food Crop Situations

Tree Nut Crops - Nuts which are washed hulled, and dehydrated before being distributed for public consumption must follow the 30-day restriction. Nuts which are harvested from the ground and sold in their shell without processing are subject to the 14-month restriction.

Sugar Beets - Sugar beets aren't expected to be eaten raw. If the beets are transported off site and considerable biosolids amended soil is carried off with them, the restrictions apply. If biosolids are left on the soil surface for 4 months or longer before being incorporated, the 20-month restriction applies. If biosolids are incorporated within 4 months of application, the 38-month restriction applies.

Tomatoes (and peppers) - Fruit often comes in contact with the ground. Tomatoes are sold both to processors and to farm stands. Tomatoes may be eaten raw by the public without further processing. The 14-month restriction applies.

503.32(b)(5)(iii): Food crops with harvested parts below the surface of the land shall not be harvested for 38 months after application of sewage sludge when the sewage sludge remains on the land surface for less than 4 months prior to incorporation into the soil.

Exposure of the surface of root crops such as potatoes and carrots to viable helminth ova is a principal concern under these circumstances. Four months is considered the minimum time for environmental conditions to reduce viable helminth ova in biosolids on the land surface. Class B biosolids incorporated into the soil surface less than 4 months after application may contain significant numbers of viable helminth ova. Once incorporated into the soil, die-off of these organisms proceeds much more slowly; therefore, a substantially longer waiting period is required to protect public health. Thirty-eight months after biosolids application is usually sufficient to reduce helminth ova to below detectable levels.

Food Crops, Feed Crops, and Fiber Crops

503.32(b)(5)(iv): Food crops, feed crops, and fiber crops shall not be harvested for 30 days after application of sewage sludge.

This restriction covers food crops that are not covered by 503.32(b)(I-iii). This would include crops with harvested parts that do not typically touch the biosolids/soil mixture and which are not collected from the ground after they have fallen from trees or plants. The restriction also applies to all feed and fiber crops. These crops may be exposed to pathogens when biosolids are applied to the land. Harvesting of these crops could result in the transport of biosolids pathogens from the growing site to the outside environment. After 30 days, however, any pathogens in biosolids that may have adhered to the crop during application will likely have been reduced to non-detectable levels. Hay, corn, soybeans, or cotton are examples of a crop covered by this restriction.

Animal Grazing

503.32(b)(5)(v): Animals shall not be allowed to graze on the land for 30 days after application of sewage sludge.

Biosolids can adhere to animals that walk on biosolids amended land and thereby be brought into potential contact with humans who come in contact with the animals (for example, horses and milking cows allowed to graze on a biosolids amended pasture). Thirty days is sufficient to substantially reduce the pathogens in surface applied biosolids, thereby significantly reducing the risk of human and animal contamination.

Turf Harvesting

503.32(b)(5)(vi): Turf grown on land where sewage sludge is applied shall not be harvested for 1 year after application of the sewage sludge when the harvested turf is placed on either land with a high potential for public exposure or a lawn, unless otherwise specified by the permitting authority.

The 1-year waiting period is designed to significantly reduce pathogens in the soil so that subsequent contact

of the turf layer will not pose a risk to public health and animals. A permitting authority may reduce this time period in cases in which the turf is not used on areas with high potential for public access.

Public Access

503.32(b)(5)(vii): Public access to land with a high potential for public exposure shall be restricted for 1 year after application of the sewage sludge.

As with the turf requirement above, a 1-year waiting period is necessary to protect public health and the environment in a potential high-exposure situation. A baseball diamond, playground, public park, or a soccer field are examples of land with a high potential for public exposure. The land gets heavy use and contact with the soil is substantial (children or ball players fall on it and dust is raised which is inhaled and ingested).

503.32(b)(5)(viii): Public access to land with a low potential for public exposure shall be restricted for 30 days after application of the sewage sludge.

A farm field used to grow corn or soybeans is an example of land with low potential for public exposure. Even farm workers and family members walk about very little on such fields. Public access restrictions do not apply to farm workers, but workers should be aware of the public health implications of land application and the land application schedule, and should follow good hygiene practice during the 30-day period. For example, workers should be instructed to wash their hands after handling soil or crops that come into contact with soil. Protective clothing and footwear are recommended for workers who work on fields that have recently been applied with Class B biosolids. More safety recommendations for workers handling biosolids are included in Section 2.2.

5.6 Domestic Septage [503.32(c)]

Under Part 503.32(c), pathogen reduction in domestic septage applied to agricultural land, forest, or reclamation sites[2] may be reduced in one of two ways:

- Either all the Class B site restrictions under 503.32(b)(5) --see Section 5.5--must be met,
- Or the pH of the domestic septage must be raised to 12 or higher by alkali addition and maintained at pH 12 or higher for 30 minutes without adding more alkali, and the site restrictions on crop harvesting in 503.32(b)(5)(I-iv) must be met (see Section 5.5). The Part 503 regulation uses the term alkali in the broad sense to mean any substance that causes an increase in pH.

Vector attraction reduction can be met with Option 9, 10, or 13. Domestic septage can be incorporated or injected into the soil to prevent vector attraction, or the pH of the domestic septage can be adjusted as outlined in Option 12 (see Section 8). pH adjustment can fulfill both pathogen and vector attraction reduction.

The pH requirement applies to every container of domestic septage applied to the land, which means that the pH of each container must be monitored. The first alternative reduces exposure to pathogens in land applied domestic septage while environmental factors attenuate pathogens. The second alternative relies on alkali treatment to reduce pathogens and contains the added safeguard of restricting crop harvesting, which prevents exposure to crops grown on domestic septage amended soils.

Chapter 6
Processes to Significantly Reduce Pathogens (PSRPs)

6.1 Introduction

Processes to Significantly Reduce Pathogens (PSRPs) are listed in Appendix B of Part 503. There are five PSRPs: aerobic and anaerobic digestion, air drying, composting, and lime stabilization. Under Part 503.32(b)(3), sewage sludge meeting the requirements of these processes is considered to be Class B with respect to pathogens (see Section 5.3). When operated under the conditions specified in Appendix B, PSRPs reduce fecal coliform densities to less than 2 million CFU or MPN per gram of total solids (dry weight basis) and reduce *Salmonella* sp. and enteric virus densities in sewage sludge by approximately a factor of 10 (Farrell, et al., 1985).

This level of pathogen reduction is required, as a minimum, by the Part 503 regulation if the sewage sludge is applied to agricultural land, a public contact site, a forest, or a reclamation site or placed on a surface disposal site[1]. Because Class B biosolids may contain some pathogens, land application of Class B biosolids is allowed only if crop harvesting, animal grazing, and public access are limited for specific periods of time following application of Class B biosolids so that pathogens can be further reduced by environmental factors (see Section 5.5).

The PSRPs listed in Part 503 are essentially identical to the PSRPs that were listed under the 40 CFR Part 257 regulation, except that all requirements related solely to reduction of vector attraction have been removed. Vector attraction reduction is now covered under separate requirements (see Chapter 8) that include some of the requirements that were part of the PSRP requirements under Part 257, as well as some new options for demonstrating vector attraction reduction. These new options provide greater flexibility to the regulated community in meeting the vector attraction reduction requirements.

Although theoretically two or more PSRP processes, each of which fails to meet its specified requirements, could be combined and effectively reduce pathogens (i.e. partial treatment in digestion followed by partial treatment by air drying) it cannot be assumed that the pathogen reduction contribution of each of the operations will result in the 2-log reduction in fecal coliform necessary to define the combination as a PSRP. Therefore, to comply with Class B pathogen requirements, one of the PSRP processes must be conducted as outlined in this chapter, or fecal coliform testing must be conducted in compliance with Class B Alternative 1. The biosolids preparer also has the option of applying for PSRP equivalency for the combination of processes. Achieving PSRP equivalency enables the preparer to stop monitoring for fecal coliform density.

This chapter provides detailed descriptions of the PSRPs listed in Appendix B. Since the conditions for the PSRPs, particularly aerobic and anaerobic digestion, are designed to meet pathogen reduction requirements, they are not necessarily the same conditions as those traditionally recommended by environmental engineering texts and manuals.

6.2 Aerobic Digestion

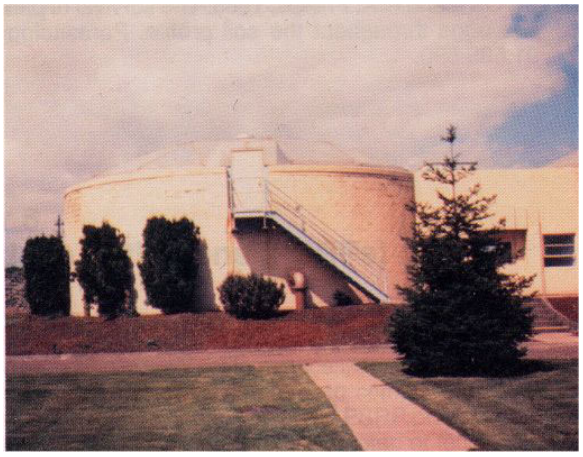
In aerobic digestion, sewage sludge is biochemically oxidized by bacteria in an open or enclosed vessel (see photo). To supply these aerobic microorganisms with enough oxygen, either the sewage sludge must be agitated by a mixer, or air must be forcibly injected (Figure 6-1). Under proper operating conditions, the volatile solids in sewage sludge are converted to carbon dioxide, water, and nitrate nitrogen.

Aerobic systems operate in either batch or continuous mode. In batch mode, the tank is filled with untreated sewage sludge and aerated for 2 to 3 weeks or longer, depending on the type of sewage sludge, ambient temperature, and average oxygen levels. Following aeration, the stabilized solids are allowed to settle and are then separated from the clarified supernatant. The process is begun again by inoculating a new batch of untreated sewage sludge with some of the solids from the previous batch to supply the necessary biological decomposers. In continuous mode, untreated sewage sludge is fed into the digester once a day or more frequently; thickened, clarified solids are removed at the same rate.

The PSRP description in Part 503 for aerobic digestion is:

- Sewage sludge is agitated with air or oxygen to maintain aerobic conditions for a specific mean cell resi-

[1]Unless the active biosolids surface disposal unit is covered at the end of each operating day, in which case no pathogen requirement applies.



Digester in Vancouver, Washington.

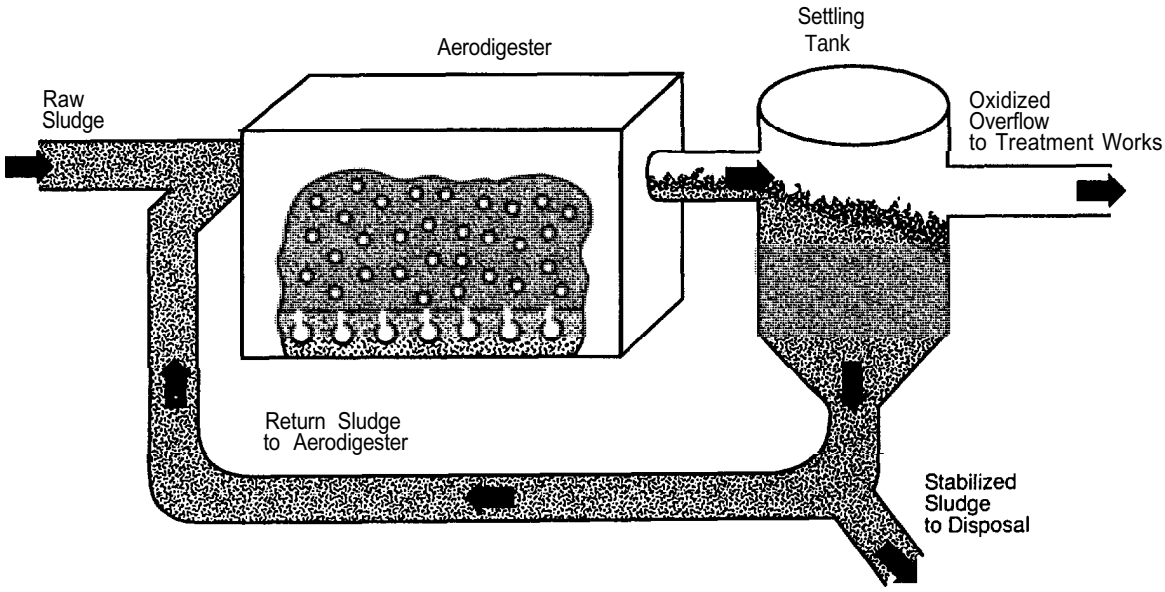


Figure 6-1. Aerobic digestion.

dence time at a specific temperature. Values for the mean cell residence time and temperature shall be between 40 days at 20°C (68°F) and 60 days at 15°C (59°F).

For temperatures between 15°C (59°F) and 20°C (68°F) use the relationship between time and temperature provided below to determine the required mean cell residence time.

$$\frac{\text{Time @T°C}}{40\ \text{d}} = 1.08\ (20\text{-}T)$$

The regulation does not differentiate between batch, intermittently fed, and continuous operation, so any method is acceptable. The mean cell residence time is considered the residence time of the sewage sludge solids. The appropriate method for calculating residence time depends on the type of digester operation used (see Appendix E).

Continuous-Mode, No Supernatant Removal For continuous-mode digesters where no supernatant is removed, nominal residence times may be calculated by dividing liquid volume in the digester by the average daily flow rate in or out of the digester.

Continuous-Mode, Supernatant Removal In systems where the supernatant is removed from the digester and recycled, the output volume of sewage sludge can be much less than the input volume of sewage sludge. For these systems, the flow rate of the sewage sludge out of the digester is used to calculate residence times.

Continuous-Mode Feeding, Batch Removal of Sewage Sludge For some aerobic systems, the digester is initially filled above the diffusers with treated effluent, and sewage sludge is wasted daily into the digester. Periodically, aeration is stopped to allow solids to settle and supernatant to be removed. As the supernatant is drawn off, the solids content in the digester gradually increases. The process is complete when either settling or supernatant removal is inadequate to provide space for the daily sewage sludge wasting requirement, or sufficient time for digestion has been provided. The batch of digested sewage sludge is then removed and the process begun again. If the daily mass of sewage sludge solids introduced has been constant, nominal residence time is one-half the total time from initial charge to final withdrawal of the digested sewage sludge.

Batch or Staged Reactor Mode A batch reactor or two or more completely-mixed reactors in series are more effective in reducing pathogens than is a single well-mixed reactor at the same overall residence time. The residence time required for this type of system to meet pathogen reduction goals may be 30% lower than the residence time required in the PSRP definition for aerobic digestion (see Appendix E). However, since lower residence times would not comply with PSRP conditions required for aerobic digestion in the regulation, approval of the process as a PSRP by the permitting authority would be required.

Other Digesters are frequently operated in unique ways that do not fall into the categories above. Appendix E provides information that should be helpful in developing a calculation procedure for these cases. Aerobic digestion carried out according to the Part 503 requirements typically reduces bacterial organisms by 2-log and viral pathogens by 1-log. Helminth ova are reduced to varying degrees, depending on the hardiness of the individual species. Aerobic digestion typically reduces the volatile solids content (the microbes' food source) of the sewage sludge by 40% to 50%, depending on the conditions maintained in the system.

Vector Attraction Reduction

Vector attraction reduction for aerobically digested sewage sludges is demonstrated either when the percent volatile solids reduction during sewage sludge treatment equals or exceeds 38%, or when the specific oxygen uptake rate (SOUR) at 20°C (68°F) is less than or equal to 1.5 mg of oxygen per hour per gram of total solids, or when additional volatile solids reduction during bench-scale aerobic batch digestion for 30 additional days at 20°C (68°F) is less than 15% (see Chapter 8).

Thermophilic aerobic systems (operating at higher temperatures) capable of producing Class A biosolids are described in Section 7.5.

6.3 Anaerobic Digestion

Anaerobic digestion is a biological process that uses bacteria that function in an oxygen-free environment to convert volatile solids into carbon dioxide, methane, and ammonia. These reactions take place in an enclosed tank (see Figure 6-2) that may or may not be heated. Because the biological activity consumes most of the volatile solids needed for further bacterial growth, microbial activity in the treated sewage sludge is limited. Currently, anaerobic digestion is one of the most widely used treatments for sewage sludge treatment, especially in treatment works with average wastewater flow rates greater than 19,000 cubic meters/day (5 million gallons per day).

Most anaerobic digestion systems are classified as either standard-rate or high-rate systems. Standard-rate systems take place in a simple storage tank with sewage sludge added intermittently. The only agitation that occurs comes from the natural mixing caused by sewage sludge gases rising to the surface. Standard-rate operation can be carried out at ambient temperature, though heat is sometimes added to speed the biological activity.

High-rate systems use a combination of active mixing and carefully controlled, elevated temperature to increase the rate of volatile solids destruction. These systems sometimes use pre-thickened sewage sludge introduced at a uniform rate to maintain constant conditions in the reactor. Operating conditions in high-rate systems foster more efficient sewage sludge digestion.

The PSRP description in Part 503 for anaerobic digestion is:

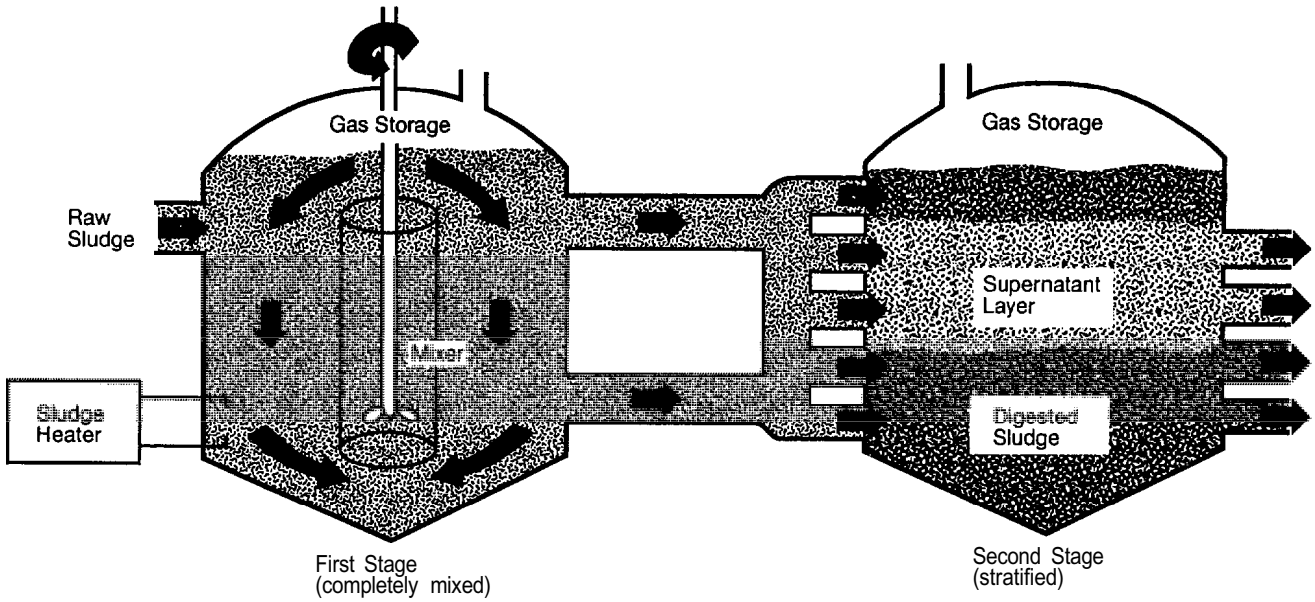

Figure 6-2. Two-stage anaerobic digestion (high rate).

- Sewage sludge is treated in the absence of air for a specific mean cell residence time at a specified temperature. Values for the mean cell residence time and temperature shall be between 15 days at 35°C to 55°C (95°F to 131°F) and 60 days at 20°C (68°F).

Straight-line interpolation to calculate mean cell residence time is allowable when the temperature falls between 35°C and 20°C.

Section 6.2 provides information on calculating residence times. Anaerobic digestion that meets the required residence times and temperatures typically reduces bacterial and viral pathogens by 90% or more. Viable helminth ova are not substantially reduced under mesophilic conditions (32°C to 38°C [90°F to 100°F]) and may not be completely reduced at temperatures between 38°C (100°F) and 50°C (122°F).

Anaerobic systems reduce volatile solids by 35% to 60%, depending on the nature of the sewage sludge and the system's operating conditions. Sewage sludges produced by systems that meet the operating conditions specified under Part 503 will typically have volatile solids reduced by at least 38%, which satisfies vector attraction reduction requirements. Alternatively, vector attraction reduction can be demonstrated by Option 2 of the vector attraction reduction requirements, which requires that additional volatile solids loss during bench-scale anaerobic batch digestion of the sewage sludge for 40 additional days at 30°C to 37°C (86°F to 99°F) be less than 17% (see Section 8.3). The SOUR test is an aerobic test and cannot be used for anaerobically digested sewage sludge.

6.4 Air Drying

Air drying allows partially digested sewage sludge to dry naturally in the open air (see photo). Wet sewage sludge is usually applied to a depth of approximately 23 cm (9 inches) onto sand drying beds, or even deeper on paved or unpaved basins. The sewage sludge is left to drain and dry by evaporation. Sand beds have an underlying drainage system; some type of mechanical mixing or turning is frequently added to paved or unpaved basins. The effectiveness of the air drying process depends very much on the local climate: drying occurs faster and more completely in warm, dry weather, and slower and less completely in cold, wet weather. During the drying/storage period in the bed, the sewage sludge is undergoing physical, chemical, and biological changes. These include biological decomposition of organic material, ammonia production, and desiccation.

Sludge drying operation. (Photo credit: East Bay Municipal Utility District)

The PSRP description in Part 503 for air drying is:

- Sewage sludge is dried on sand beds or on paved or unpaved basins. The sewage sludge dries for a minimum of 3 months. During 2 of the 3 months, the ambient average daily temperature is above 0°C (32°F).

Although not required by the Part 503, it is advisable to ensure that the sewage sludge drying beds are exposed to the atmosphere (i.e., not covered with snow) during the 2 months that the daily temperature is above 0°C (32°F). Also, the sewage sludge should be at least partially digested before air drying. Under these conditions, air drying will reduce the density of pathogenic viruses by 1-log and bacteria by approximately 2-log. Viable helminth ova also are reduced, except for some hardy species that remain substantially unaffected.

Vector Attraction Reduction

Frequently sand-bed drying follows an aerobic or anaerobic digestion process that does not meet the specified process requirements and does not produce 38% volatile solids destruction. However, it may be that the volatile solids reduction produced by the sequential steps of digestion and drying will meet the vector attraction reduction requirement of 38% volatile solids reduction. If this is the case, vector attraction reduction requirements are satisfied.

Example of Meeting PSRP and Vector Attraction Reduction Requirements

Type of Facility	Air Drying
Class	B
Pathogen Reduction	Partially digested sewage sludge is thickened and spread in drying beds. Filling of beds starts in June, and the beds accommodate sewage sludge generated over 1 full year. Beds are then emptied the following September so that all sewage sludge is retained over an entire summer (>0°C ambient temperatures).
Testing	Sewage sludge is tested for pollutants 2 weeks before material is removed and distributed.
Vector Attraction Reduction	Biosolids are land applied and plowed immediately into the soil.
Use or Disposal	Biosolids are delivered to local farmers. Farmers are given information on site restrictions, and must follow harvest, grazing, and public access restrictions.

Vector Attraction Reduction

Air-dried sewage sludge typically is treated by aerobic or anaerobic digestion before it is placed on drying beds. Usually, the easiest vector attraction reduction requirement to meet is a demonstration of 38% reduction in volatile solids (Option 1, See Section 8.2), including the reduction that occurs during its residence on the drying beds.

In dry climates, vector attraction reduction can be achieved by moisture reduction (see Option 7 in Section 8.8, and Option 8 in Section 8.9).

6.5 Composting

Composting involves the aerobic decomposition of organic material using controlled temperature, moisture, and oxygen levels. Several different composting methods are currently in use in the United States. The three most common are windrow, aerated static pile, and within-vessel composting. These are described below.

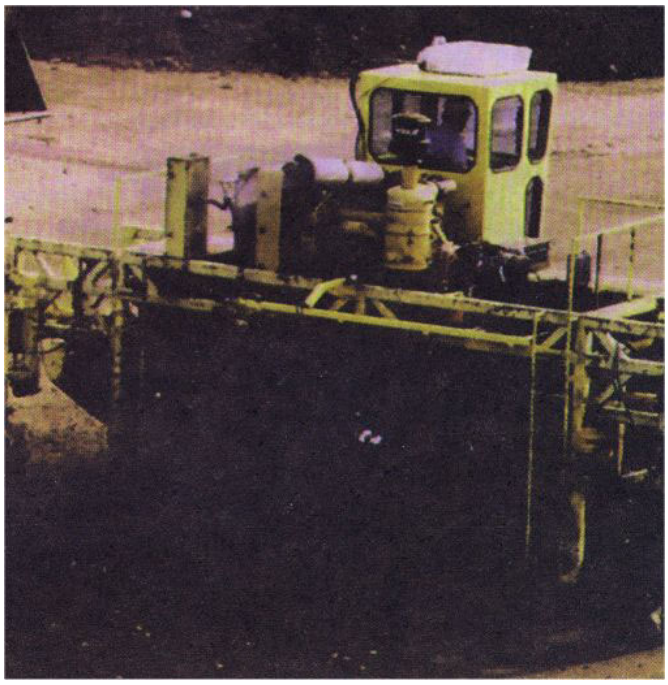
Composting can yield either Class A or Class B biosolids, depending on the time and temperature variables involved in the operation.

All composting methods rely on the same basic processes. Bulking agents such as wood chips, bark, sawdust, straw, rice hulls, or even-finished compost are added to the sewage sludge to absorb moisture, increase porosity, and add a source of carbon. This mixture is stored (in windrows, static piles, or enclosed tanks) for a period of intensive decomposition, during which temperatures can rise well above 55°C (131°F). Depending on ambient temperatures and the process chosen, the time required to reduce pathogens and produce Class B biosolids can range from 3 to 4 weeks. Aeration and/or frequent mixing or turning are needed to supply oxygen and remove excess heat. Following this active stage, bulking agents may or may not be screened from the completed compost for recycling (see photo), and the composted biosolids are “cured” for an additional period.

Windrow composting involves stacking the sewage sludge/bulking agent mixture into long piles, or windrows, generally 1.5 to 2.7 meters high (5 to 9 feet) and 2.7 to 6.1 meters wide (9 to 20 feet). These rows are regularly turned or mixed with a turning machine or front-end loader to fluff up the material and increase porosity which allows better convective oxygen flow into the material. Turning also breaks up compacted material and reduces the moisture content of the composting media (see photo, next page). Active windrows are typically placed in the open air, except in areas with heavy rainfall. In colder climates, winter weather can significantly increase the amount of time needed to attain temperatures needed for pathogen reduction.

Aerated static pile composting uses forced-air rather than mechanical mixing (see Figure 6-3) to both supply sufficient oxygen for decomposition and carry off moisture. The sewage sludge/bulking agent mixture is placed on top of

Composted sludge is screened to remove the bulking agent prior to land application



Compost mixing equipment turns over a windrow of compost for solar drying prior to screening [Photo credit: East Bay Municipal Utility District)

either (1) a fixed underlying forced aeration system, or (2) a system of perforated piping laid on the composting pad surface and topped with a bed of bulking agent. The entire pile is covered with a layer of cured compost for insulation and odor control. Pumps are used to blow air into the compost pile or suck air through it. The latter provides greater odor control because the compost air can be easily collected and then filtered or scrubbed.

Within-vessel composting systems vary greatly in design, but they share two basic techniques: the process takes place in a reactor vessel where the operating conditions can be carefully controlled (see photo page 49), and active aeration meets the system's high oxygen demand. Agitated bed systems (one type of within-vessel composting) depend on continuous or periodic mixing within the vessel, followed by a curing period.

Pathogen reduction during composting depends on time and temperature variables (see photo page 49). Part 503 provides the following definition of PSRP requirement for pathogen reduction during composting:

- Using either the within-vessel, static aerated pile, or windrow composting methods, the temperature of the sewage sludge is raised to 40°C (104°F) or higher and remains at 40°C (104°F) or higher for 5 days. For 4 hours during the 5-day period, the temperature in the compost pile exceeds 55°C (131°F).

These conditions, achieved using either within-vessel, aerated static pile, or windrow methods, reduce bacterial pathogens by 2-log and viral pathogens by 1-log.

A process time of only 5 days is not long enough to fully break down the volatile solids in sewage sludge, so the composted sewage sludge produced under these conditions will not be able to meet any of the requirements for reduced vector attraction. In addition, sewage sludge that has been composted for only 5 days may still be odorous. Breakdown of volatile solids may require 14 to 21 days for within-vessel; 21 or more days for aerated static pile; and 30 or more days for windrow composting. Many treatment works allow the finished sewage sludge compost to further mature or cure for at least several weeks following active composting during which time pile turning or active aeration may continue.

Composting is most often used to meet Class A requirements. More guidance for composting operations and how to meet Class A time and temperature requirements is provided in Chapter 7.

Vector Attraction Reduction

Vector attraction reduction must be conducted in accordance with Option 5, or compost must be incorporated into soil when land applied. This option requires aerobic treatment (i.e., composting) of the sewage sludge for at least 14 days at over 40°C (104°F) with an average temperature of over 45°C (113°F).

6.6 Lime Stabilization

The lime stabilization process is relatively straightforward: lime — either hydrated lime, $Ca(OH)_2$; quicklime, CaO; or lime containing kiln dust or fly ash — is added to sewage sludge in sufficient quantities to raise the pH above 12 for 2 hours or more after contact, as specified in the Part 503 PSRP description for lime stabilization:

- Sufficient lime is added to the sewage sludge to raise the pH of the sewage sludge to 12 after 2 hours of contact.

For the Class B lime stabilization process, the alkaline material must be a form of lime. Use of other alkaline ma-

Taulman Weiss in-vessel composting facility in Portland, Oregon.

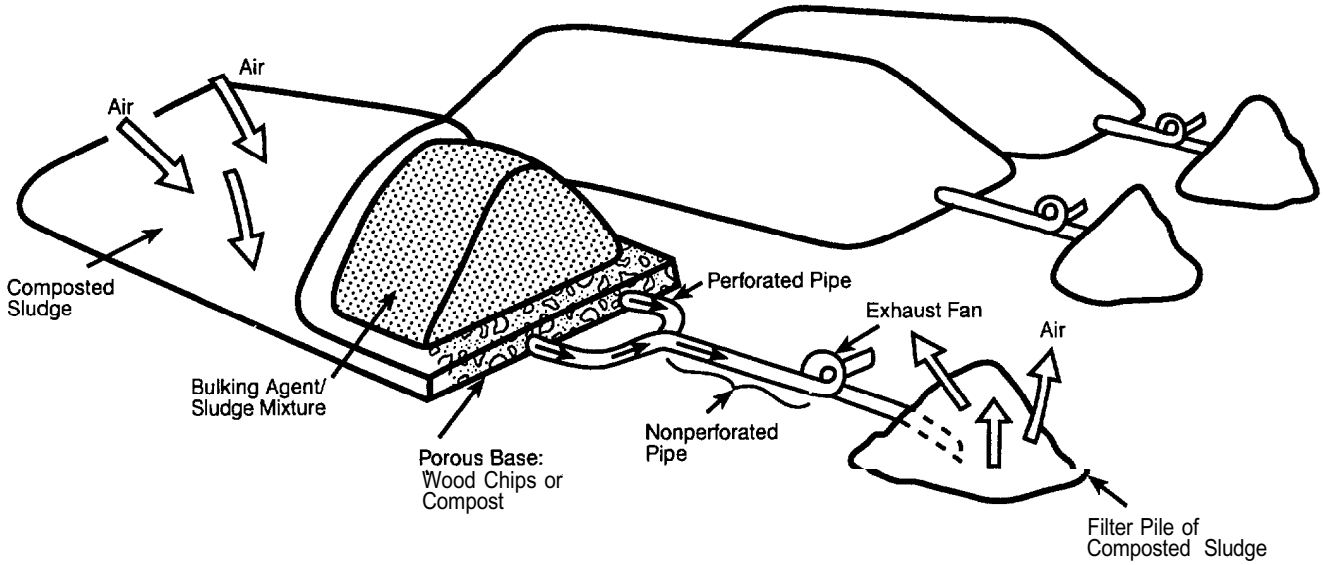

Figure 6-3. Static aerated pile composting.

terials must first be demonstrated to be equivalent to a PSRP. Elevation of pH to 12 for 2 hours is expected to reduce bacterial and viral density effectively.

Lime may be introduced to liquid sewage sludge in a mixing tank or combined with dewatered sewage sludge, providing the mixing is complete and the sewage sludge cake is moist enough to allow aqueous contact between the sewage sludge and lime.

Mixing must be sufficient to ensure that the entire mass of sewage sludge comes into contact with the lime and undergoes the increase in pH and to ensure that samples are representative of the overall mixture (see Chapter 9). pH should be measured at several locations to ensure that the pH is raised throughout the sewage sludge.

A variety of lime stabilization processes are currently in use. The effectiveness of any lime stabilization process for controlling pathogens depends on maintaining the pH at levels that reduce microorganisms in the sewage sludge. Field experience has shown that the application of lime stablized material after the pH has dropped below 10.5 may, in some cases, create odor problems. Therefore it is

recommended that biosolids application take place while the pH remains elevated. If this is not possible, and odor problems develop, alternate management practices in the field include injection or incorporation or top dressing the applied biosolids with additional lime. Alternate management practices if the biosolids have not yet left the wastewater treatment plant may include adding additional lime to maintain the elevated pH or additional treatment through drying or composting. Lime stabilization can reduce bacterial and viral pathogens by 99% or more. Such alkaline conditions have little effect on hardy species of helminth ova, however.

Vector Attraction Reduction

For lime-treated sewage sludge, vector attraction reduction is best demonstrated by Option 6 of the vector attraction reduction requirements. This option requires that the sewage sludge pH remain at 12 or higher for at least 2 hours, and then at 11.5 or more for an additional 22 hours (see Section 8.7).

Lime stabilization does not reduce volatile solids. Field experience has shown that the application of lime stabilized material after the pH has dropped below 10.5 may create odor problems. Therefore it is recommended that land application of biosolids take place as soon as possible after vector attraction reduction is completed and while pH remains elevated.

6.7 Equivalent Processes

Table 11.1 in Chapter 11 lists some of the processes that the EPA's Pathogen Equivalency Committee has recommended as being equivalent to PSRP under Part 257. Information on the PEC and how to apply for equivalency are discussed in Chapter 11.

Chapter 7
Processes to Further Reduce Pathogens (PFRPs)

7.1 Introduction

Processes to Further Reduce Pathogens (PFRPs) are listed in Appendix B of the Part 503. There are seven PFRPs: composting, heat drying, heat treatment, thermophilic aerobic digestion, beta ray irradiation, gamma ray irradiation, and pasteurization. When these processes are operated under the conditions specified in Appendix B, pathogenic bacteria, enteric viruses, and viable helminth ova are reduced to below detectable levels. The PFRPs listed in Part 503 are essentially identical to the PFRPs listed under the 40 CFR Part 257 regulation, except that all requirements related solely to reduction of vector attraction have been removed.

This chapter provides detailed descriptions of the seven PFRPs listed in Part 503. Because the purpose of these processes is to produce Class A biosolids, the pathogen reduction process must be conducted concurrent to or prior to the vector attraction reduction process (see Section 4.2).

Under Part 503.32(a)(7), sewage sludge treated in these processes is considered to be Class A with respect to helminth ova, enteric viruses, and pathogenic bacteria. In addition, Class A biosolids must be monitored for fecal coliform or *Salmonella* sp. bacteria at the time of use on disposal, at the time the biosolids are prepared for sale or give away in a bag or other container for land application, or at the time the biosolids are prepared to meet the requirements for "exceptional quality" sludge (see Chapter 2) in 503.10(b), 503.10(c), 503.10(e), or 503.10(f) to ensure that growth of bacteria has not occurred (see Section 4.3). Guidelines regarding the frequency of pathogen sampling and sampling protocols are included in Chapter 9.

7.2 Composting

Composting is the controlled, aerobic decomposition of organic matter which produces a humus-like material. Sewage sludge which is to be composted is generally mixed with a bulking agent such as wood chips which increases porosity in the sewage sludge, allowing air to more easily pass through the composting material and maintain aerobic conditions. There are three commonly used methods of composting: windrow, static aerated pile, and within-vessel.

To be considered a PFRP under Part 503, the composting operation must meet certain operating conditions:

- Using either the within-vessel composting method or the static aerated pile composting method, the temperature of the sewage sludge is maintained at 55°C (131°F) or higher for 3 consecutive days.
- Using the windrow composting method, the temperature of the sewage sludge is maintained at 55°C (131°F) or higher for 15 consecutive days or longer. During the period when the compost is maintained at 55°C (131°F) or higher, there shall be a minimum of five turnings of the windrow.

For aerated static pile and in-vessel composting processes, temperatures should be taken at multiple points at a range of depths throughout the composting medium. Points which are likely to be slightly cooler than the center of the pile, such as the toes of piles, also should be monitored. Because the entire mass of sewage sludge must attain the required temperatures for the required duration, the temperature profiles from every monitoring point, not just the average of the points, should reflect PFRP conditions.

It has been found that points within 0.3 m (1 foot) of the surface of aerated static piles may be unable to reach PFRP temperatures, and for this reason, it is recommended that a 0.3 m (1 foot) or greater layer of insulating material be placed over all surfaces of the pile. Finished compost is often used for insulation. It must be noted that because the insulation will most likely be mixed into the composted material during post-processing or curing, compost used as an insulation material must be a Class A material so as not to reintroduce pathogens into the composting sewage sludge.

For windrow composting, the operational requirements are based on the same time-temperature relationship as aerated static pile and in-vessel composting. The material in the core of the windrow attains at least 55°C and must remain at that temperature for 3 consecutive days. Windrow turning moves new material from the surface of the windrow into the core so that this material may also undergo pathogen reduction. After five turnings, all material in the windrow must have spent 3 days at the core of the pile. The time-temperature regime takes place over a period of at least 15 consecutive days during which time the temperature in the core of the windrow is at least 55°C. See Appendix J for additional guidance.

Pathogen reduction is a function of three parameters:

- Ensuring that all sewage sludge is mixed into the core of the pile at some point during active composting
- Ensuring that all sewage sludge particles spend 3 consecutive days in the core during which time the temperatures are at 55°C
- Preventing growth of pathogenic bacteria in composted material

The first issue, ensuring that all material is mixed into the core of the pile, depends on the configuration of the windrows and the turning methodology. Pile size and shape as well as material characteristics determine how much of the pile is in the "hot zone" at any given time. Additional turning and maintenance of temperatures after the mandated 15 days are recommended, depending on the windrow configuration. For example, the Los Angeles County Sanitation District found that as many as 12-15 turnings were necessary to reduce pathogens in windrow composted sewage sludge (Personal Communication, Ross Caballero, Los Angeles County Sanitation District, 1998).

Second, it is important that once that material is in the pile core it be subject to the full time-temperature regime necessary to reduce pathogens. Therefore, the turning schedule and the recovery of the core zone to 55°C are important factors. If pile turning is not evenly distributed throughout the 15-day period, some material may not spend adequate time in the core of the pile. Additionally, pile temperatures generally drop off immediately after turning; if temperatures in the pile core do not quickly recover to 55°C (within 24 hours), the necessary pathogen reduction period of 3 days will not be achieved.

Because of the operational variability, pathogen reduction in windrow composting has been found to be less predictable than pathogen reduction in aerated static pile or in-vessel composting. In order to improve pathogen reduction, the following operational guidelines are recommended.

- Windrow turning should take place after the pile core has met pathogen reduction temperatures for 3 consecutive days. Windrow turnings should be evenly spaced within the 15 days so that all material remains in the core zone for 3 consecutive days; allowing additional time as needed for the core temperature to come up to 55°C.
- Pathogen reduction temperatures (55°C) must be met for 15 consecutive days at the pile core.
- Temperatures should be taken at approximately the same time each day in order to demonstrate that 55°C has been reached in the pile core within 24 hours after pile turning.
- Testing frequency should be increased; a large sewage sludge windrow composting operation recommends testing each windrow for *Salmonella* sp. before piles are distributed (Personal Communication, Ross Caballero, Los Angeles County Sanitation District, 1998). Samples are taken after turning is completed, and piles which do not comply with Class A requirements are retained on site for further composting.

Vector Attraction Reduction (VAR)

The options for demonstrating vector attraction reduction for both PFRP and PSRP composting are the same. Option 5 is the most appropriate for composting operations. This option requires aerobic treatment (e.g. composting) of the sewage sludge for at least 14 consecutive days at over 40ºC (104°F) with an average temperature of over 45ºC (113°F). This is usually easily attained by sewage sludge composting.

The PFRP and VAR requirements can be met concurrently in composting. For within-vessel or aerated static pile composting, the temperature profile should show PFRP temperatures at each of the temperature monitoring points for 3 consecutive days, followed by a minimum of 11 more days during which time the average temperature of the pile complies with VAR requirements. For windrow piles, the compliance with PFRP temperatures will also fulfill VAR requirements.

PFRP temperatures should be met before or at the same time that VAR requirements are fulfilled in order to reduce the potential for pathogen regrowth. However, continued curing of the composting material will most likely further prevent the growth of pathogenic bacteria from taking place.

Like all microbiological processes, composting can only take place with sufficient moisture (45-60%). Excessive aeration of composting piles or arid ambient condition may dry composting piles to the point at which microbial activity slows or stops. The cessation of microbial activity results in lowered pile temperatures which can easily be mistaken for the end-point of composting. Although composting may appear to have ended, and compost may even meet vector attraction reduction via Option 7, overly dried compost can cause both odor problems and vector attraction if moisture is reintroduced into the material and microbial activity resumes. It is therefore recommended that the composting process be maintained at moisture levels between 45-60% (40-55% total solids) (Epstein, 1997).

Microbiological Requirements

If the conditions specified by the Part 503 regulation are met, all pathogenic viruses, bacteria, and parasites will be reduced to below detectable levels. However, it may be difficult to meet the Class A microbiological requirement for fecal coliforms even when *Salmonella* sp. bacteria are not present. Biological sewage sludge treatment processes involving high temperatures, such as composting, can reduce *Salmonella* sp. to below detectable levels while leaving some surviving fecal coliforms. If sufficient nutrients remain in the sewage sludge, bacteria can later grow to

significant numbers. It may be preferable, therefore, to test composted sewage sludge directly for *Salmonella* sp., rather than using fecal coliforms as an indicator of pathogen control.

Although not mandated by the Part 503 regulation, compost is usually maintained on site for longer than the required PFRP and VAR duration. In order to produce a high-quality, marketable product, it has been found that a curing period, or the period during which the volatile solids in the sewage sludge continue to decompose, odor potential decreases, and temperatures decrease into the mesophilic (40-45°C) range, is necessary. Depending on the feedstock and the particular process, the curing period may last an additional 30 - 50 days after regulatory requirements are met.

In general, compost is not considered marketable until the piles are no longer self-heating. It is important to note that compost piles that are cooled by excessive aeration or that do not self-heat because the material is too dry to support microbial activity may not actually be fully decomposed.

It has been found that further reduction of organic material takes place during the curing phase of composting (Epstein, 1997). Therefore microbiological testing should take place at the end of the curing process when compost is prepared for sale or distribution. Compost which is stored on site for extended periods of time until it can be sold or distributed must be tested for compliance with microbiological limits when it is to be used or disposed.

7.3 Heat Drying

Heat drying is used to reduce both pathogens and the water content of sewage sludge. The Part 503 PFRP description of heat drying is:

- Sewage sludge is dried by direct or indirect contact with hot gases to reduce the moisture content to 10% or lower. Either the temperature of the sewage sludge particles exceeds 80°C (176°F) or the wet bulb temperature of the gas in contact with the sewage sludge as it leaves the dryer exceeds 80°C (176°F).

Properly conducted heat drying will reduce pathogenic viruses, bacteria, and helminth ova to below detectable levels. Four processes are commonly used for heat drying sewage sludge: flash dryers, spray dryers, rotary dryers, and steam dryers. Flash dryers used to be the most common heat drying process installed at treatment works, but current practice favors rotary dryers. These processes are briefly described below. More detailed descriptions are provided in EPA's Process Design Manual (EPA, 1979).

Flash Dryers

Flash dryers pulverize sewage sludge in the presence of hot gases. The process is based on exposing fine sewage sludge particles to turbulent hot gases long enough to attain at least 90% solids content.

Spray Dryers

A spray dryer typically uses centrifugal force to atomize liquid sewage sludge into a spray that is directed into a drying chamber. The drying chamber contains hot gases that rapidly dry the sewage sludge mist. Some spray drying systems use a nozzle to atomize sewage sludge.

Rotary Dryers

Rotary dryers function as horizontal cylindrical kilns. The drum rotates and may have plows or louvers that mechanically mix the sewage sludge as the drum turns. There are many different rotary kiln designs, utilizing either direct heating or indirect heating systems. Direct heating designs maintain contact between the sewage sludge and the hot gases. Indirect heating separates the two with steel shells.

Steam Dryers

Indirect steam dryers utilize steam to heat the surface of the dryers which will come into contact with the sewage sludge. The heat transfer surface may consist of discs or paddles, which rotate to increase their contact with the sewage sludge.

Vector Attraction Reduction

No further processing is required because the PFRP requirements for heat drying also meet the requirements of Option 8 for vector attraction reduction (the percent solids must be at least 90% before mixing the sewage sludge with other materials). This fulfills the requirement of Option 7 if the sewage sludge being dried contains no unstabilized solids.

Drying of sewage sludge to 90% solids deters the attraction of vectors, however, unstabilized dried biosolids which are rewet may become odorous and attract vectors. Therefore, it is recommended that materials be used or disposed while the level of solids remains high and that dried material be stored and maintained under dry conditions.

Some operators have found that maintaining stored material at solids levels above 95% helps to deter reheating because microbiological activity is halted. However, storage of materials approaching 90% total solids can lead to spontaneous combustion with subsequent fires and risk of explosion. While there is little likelihood of an explosion occurring with storage of materials like pellets, precautionary measures such as maintaining proper oxygen levels and minimizing dust levels in storage silos and monitoring temperatures in material can reduce the risk of fires.

Microbiological Requirements

Heat dried biosolids must be tested for fecal coliform or *Salmonella* sp. at the last point before being used or disposed. For example, biosolids should be tested immediately before they are bagged or before they leave the site for bulk distribution. If material is stored for a long period of time, it should be re-tested, even if previous testing has

shown the biosolids to have met the Part 503 regulation. This is particularly important if material has been rewetted.

7.4 Heat Treatment

Heat treatment processes are used to disinfect sewage sludge and reduce pathogens to below detectable levels. The processes involve heating sewage sludge under pressure for a short period of time. The sewage sludge becomes sterilized and bacterial slime layers are solubilized, making it easier to dewater the remaining sewage sludge solids. The Part 503 PFRP description for heat treatment is:

- Liquid sewage sludge is heated to a temperature of 180°C (356°F) or higher for 30 minutes.

Two processes have principally been used for heat treating sludge in preparation for dewatering: the Porteous and the Zimpro process. In the Porteous process the sewage sludge is preheated and then injected into a reactor vessel. Steam is also injected into the vessel under pressure. The sewage sludge is retained in the vessel for approximately 30 minutes after which it is discharged to a decant tank. The resulting sewage sludge can generally be concentrated and dewatered to high solids concentrations. Further dewatering may be desirable to facilitate sewage sludge handling.

The Zimpro process is similar to the Porteous process. However, air is injected into the sewage sludge before it enters the reactor and the vessel is then heated by steam to reach the required temperature. Temperatures and pressures are approximately the same for the two processes.

Vector Attraction Reduction

Heat treatment in most cases must be followed by vector attraction reduction. Vector attraction reduction Options 6 to 11 (pH adjustment, heat drying, or injection, incorporation, or daily cover) may be used (see Chapter 8). Options 1 through 5 would not typically be applicable to heat treated sludge unless the sludge was digested or otherwise stabilized during or after heat treatment (e.g. through the use of wet air oxidation during heat treatment).

Microbiological Requirements

When operated according to the Part 503 requirements, the process effectively reduces pathogenic viruses, bacteria, and viable helminth ova to below detectable levels. Sewage sludge must be properly stored after processing because organic matter has not been reduced, and therefore, growth of bacteria can occur.

Heat treated sewage sludge must be tested for fecal coliform or *Salmonella* sp. at the time of use or disposal or as it is prepared for sale or distribution. If heat treated biosolids are subsequently composted or otherwise treated, pathogen testing should take place after that processing is complete.

7.5 Thermophilic Aerobic Digestion

Thermophilic aerobic digestion is a refinement of the conventional aerobic digestion processes discussed in Section 6.2. In this process, feed sewage sludge is generally pre-thickened and an efficient aerator is used. In some modifications, oxygen is used instead of air. Because there is less sewage sludge volume and less air to carry away heat, the heat released from biological oxidation warms the sewage sludge in the digester to as high as 60°C (140°F).

Because of the increased temperatures, this process achieves higher rates of organic solids reduction than are achieved by conventional aerobic digestion which operates at ambient air temperature. The biodegradable volatile solids content of the sewage sludge can be reduced by up to 70% in a relatively short time. The digested sewage sludge is effectively pasteurized due to the high temperatures. Pathogenic viruses, bacteria, viable helminth ova and other parasites are reduced to below detectable limits if the process is carried out at temperatures exceeding 55°C (131°F).

This process can either be accomplished using auxiliary heating of the digestion tanks or through special designs that allow the energy naturally released by the microbial digestion process to heat the sewage sludge. The Part 503 PFRP description of thermophilic aerobic digestion is:

- Liquid sewage sludge is agitated with air or oxygen to maintain aerobic conditions and the mean cell residence time of the sewage sludge is 10 consecutive days at 55°C to 60°C (131°F to 140°F).

The thermophilic process requires significantly lower residence times (i.e., solids retention time) than conventional aerobic processes designed to qualify as a PSRP, which must operate 40 to 60 days at 20°C to 15°C (68°F to 59°F), respectively. Residence time is normally determined by dividing the volume of sewage sludge in the vessel by the volumetric flow rate. Facility operation should minimize the potential for bypassing by withdrawing treated sewage sludge before feeding, and feeding no more than once a day.

In the years following the publication of the Part 503 regulation, advances in thermophilic digestion have been made. It should be noted, however, that complete-mix reactors with continuous feeding may not be adequate to meet Class A pathogen reduction because of the potential for bypassing or short-circuiting of untreated sewage sludge.

Vector Attraction Reduction

Vector attraction reduction must be demonstrated. Although all options, except Options 2, 4, and 12 are possible, Options 1 and 3 which involve the demonstration of volatile solids loss are the most suitable. (Option 2 is appropriate only for anaerobically digested sludge, and Option 4 is not possible because it is not yet known how to translate SOUR measurements obtained at high temperatures to 20°C [68°F].)

Thermophilically aerobically digested biosolids must be tested for fecal coliform or *Salmonella* sp. at the time of

use or disposal or as it is prepared for sale or distribution. If digested biosolids are subsequently composted or otherwise treated, pathogen testing for either fecal coliform or *Salmonella* sp. should take place after processing is complete.

7.6 Beta Ray and Gamma Ray Radiation

Radiation can be used to disinfect sewage sludge. Radiation destroys certain organisms by altering the colloidal nature of the cell contents (protoplasm). Gamma rays and beta rays are the two potential energy sources for use in sewage sludge disinfection. Gamma rays are high-energy photons produced by certain radioactive elements. Beta rays are electrons accelerated in velocity by electrical potentials in the vicinity of 1 millions volts. Both types of radiation destroy pathogens that they penetrate if the doses are adequate. The Part 503 PFRP descriptions for irradiation systems are:

Beta Ray Irradiation

- Sewage sludge is irradiated with beta rays from an accelerator at dosages of at least 1.0 megarad at room temperature (ca. 20°C [68°F]).

Gamma Ray Irradiation

- Sewage sludge is irradiated with gamma rays from certain isotopes, such as Cobalt 60 and Cesium 137 [at dosages of at least 1.0 megarad] at room temperature (ca. 20°C [68°F]).

The effectiveness of beta radiation in reducing pathogens depends on the radiation dose, which is measured in rads. A dose of 1 megarad or more will reduce pathogenic viruses, bacteria, and helminths to below detectable levels. Lower doses may successfully reduce bacteria and helminth ova but not viruses. Since organic matter has not been destroyed with processing, sewage sludge must be properly stored after processing to prevent contamination.

Although the two types of radiation function similarly to inactivate pathogens, there are important differences. Gamma rays can penetrate substantial thicknesses of sewage sludge and can therefore be introduced to sewage sludge by either piping liquid sewage sludge into a vessel that surrounds the radiation source (Figure 7-1) or by carrying composted or dried sewage sludge by hopper conveyor to the radiation source. Beta rays have limited penetration ability and therefore are introduced by passing a thin layer of sewage sludge under the radiation source (Figure 7-2).

Vector Attraction Reduction

Radiation treatment must be followed by vector attraction reduction. The appropriate options for demonstrating vector attraction reduction are the same as for heat treatment (see Section 7.4), namely Options 6 to 11. Options 1-5 are not applicable unless the sewage sludge is subsequently digested.

Microbiological Requirements

Irradiated sewage sludge must be tested for fecal coliform or *Salmonella* sp. at the time of use or disposal or as it is prepared for sale or distribution.

7.7 Pasteurization

Pasteurization involves heating sewage sludge to above a predetermined temperature for a minimum time period. For pasteurization, the Part 503 PFRP description is:

- The temperature of the sewage sludge is maintained at 70°C (158°F) or higher for 30 minutes or longer.

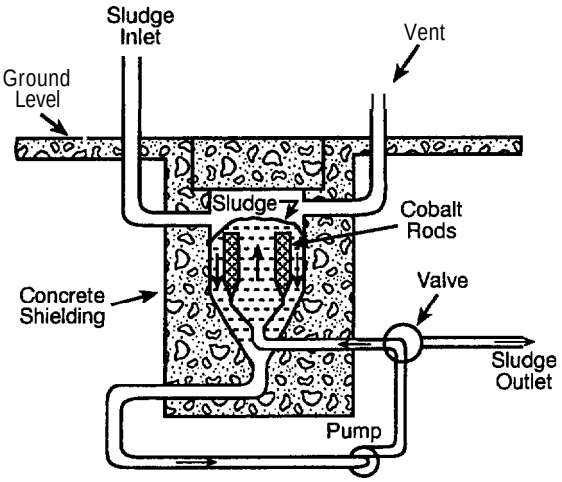

Figure 7-1. Schematic representation of cobalt-60 (gamma ray) irradiation facility at Geiselbullach, Germany. Source: EPA. 1979.

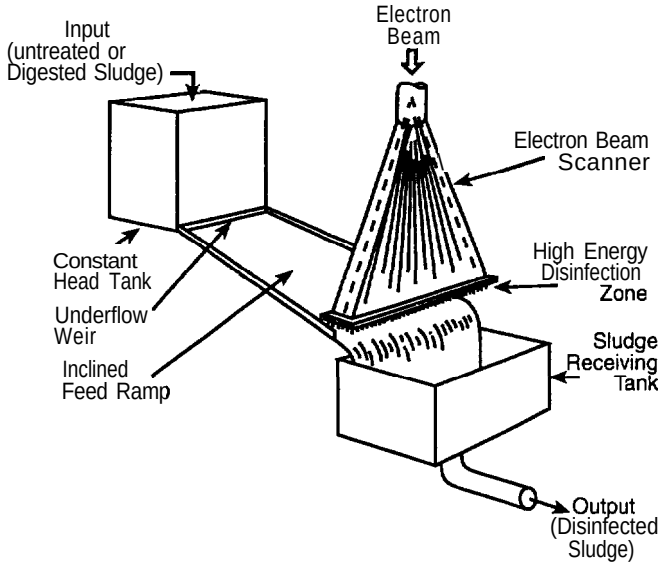

Figure 7-2. Beta ray scanner and sludge spreader. Source: EPA,1979.

Pasteurization reduces bacteria, enteric viruses, and viable helminth ova to below detectable values. Sewage sludge can be heated by heat exchangers or by steam injection. Although sewage sludge pasteurization is uncommon in the United States, it is widely used in Europe. The steam injection method is preferred because it is more effective at maintaining even temperatures throughout the sewage sludge batch being processed. Sewage sludge is pasteurized in batches to prevent recontamination that might occur in a continuous process. Sewage sludge must be properly stored after processing because the organic matter has not been stabilized and therefore odors and growth of pathogenic bacteria can occur if sewage sludge is re-inoculated.

In theory, quicklime can be used to meet the requirements for pasteurization of sewage sludge. The water in the sludge slakes the lime, forming calcium hydroxide, and generates heat. However, it is difficult to ensure that the entire mass of sewage sludge comes into contact with the lime and achieves the required 70°C for 30 minutes. This is particularly true for dewatered sewage sludges. Processes must be designed to 1) maximize contact between the lime and the sewage sludge, 2) ensure that adequate moisture is present, 3) ensure that heat loss is minimal, and 4) if necessary, provide an auxiliary heat source. Pasteurization cannot be accomplished in open piles.

In addition, in order for pasteurization to be conducted properly, facility operators must be trained with regard to 1) the proper steps to be taken to ensure complete hydration of the alkaline reagent used, 2) the evaluation of the slaking rate of the lime-based alkaline material required for their particular process, specifying the reactivity rate required, 3) the proper measurement of pH, 4) an awareness of the effect of ammonia gassing off and how this affects the lime dose, and 5) the necessity for maintaining sufficient moisture in the sewage sludge/alkaline mixture during the mixing process to ensure the complete hydration of the quicklime and migration of hydroxyl ions throughout the sewage sludge mass. This is to ensure that the entire sewage sludge mass is disinfected.

EPA-sponsored studies showed that pasteurization of liquid sewage sludge at 70°C (158°F) for 30 minutes inactivates parasite ova and cysts and reduces the population of measurable viruses and pathogenic bacteria to below detectable levels (U.S. EPA, 1979). This process is based on the pasteurization of milk which must be heated to at least 63°C (145°F) for at least 30 minutes.

Vector Attraction Reduction

Pasteurization must be followed by a vector attraction reduction process unless the vector attraction reduction conditions of Option 6 (pH adjustment) have been met. The options appropriate for demonstrating vector attraction reduction are the same as those for heat treatment (see Section 10.4), namely Options 6 to 11. Options 1 to 5 are not applicable unless the sludge is subsequently digested.

Microbiological Requirements

Pasteurized sludge must be tested for fecal coliform or *Salmonella* sp. at the time of use or disposal or as it is prepared for sale or distribution. In Europe, serious problems with regrowth of *Salmonella* sp. have occurred, so pasteurization is rarely used now as a terminal treatment process. Pre-pasteurization followed by mesophilic digestion has replaced the use of pasteurization after digestion in many European communities.

7.8 Equivalent Processes

Under Class A Alternative 6, sewage sludge treated in processes that are determined to be equivalent to PFRP are considered to be Class A with respect to pathogens (assuming the treated sewage sludges also meet the Class A microbiological requirement). Table 11-2 in Chapter 11 lists some of the processes that were found, based on the recommendation of EPA's Pathogen Equivalency Committee, to be equivalent to PFRP under Part 257. Chapter 11 discusses how the PEC makes a recommendation of equivalency.

Chapter 8
Requirements for Reducing Vector Attraction

8.1 Introduction

The pathogens in sewage sludge pose a disease risk only if there are routes by which the pathogens are brought into contact with humans or animals. A principal route for transport of pathogens is vector transmission. Vectors are any living organism capable of transmitting a pathogen from one organism to another either mechanically (by simply transporting the pathogen) or biologically by playing a specific role in the life cycle of the pathogen. Vectors for sewage sludge pathogens would most likely include insects, rodents, and birds.

Suitable methods for measuring vector attraction directly are not available. Vector attraction reduction is accomplished by employing one of the following:

- Biological processes which breakdown volatile solids, reducing the available food nutrients for microbial activities and odor producing potential
- Chemical or physical conditions which stop microbial activity
- Physical barriers between vectors and volatile solids in the sewage sludge

At the present time there is no vector attraction equivalency committee that evaluates other options for vector attraction reduction. The creation of one is being considered. The specific options outlined in the Part 503 regulation are currently the only available means for demonstrating vector attraction reduction.

The term “stability” is often used to describe sewage sludge. Although it is associated with vector attraction reduction, stability is not regulated by the Part 503 Rule. With regard to sewage sludge, stability is generally defined as the point at which food for rapid microbial activity is no longer available. Sewage sludge which is stable will generally meet vector attraction reduction (VAR) requirements. The converse is not necessarily true; meeting VAR requirements does not ensure sewage sludge stability. Because stability is also related to odor generation and the continued degradation of sewage sludge, it is often considered an important parameter when producing biosolids for sale or distribution. Table 8-1 lists some of the common methods for measuring stability.

Table 8-1. Stability Assessment

Process	Monitoring Methods
Composting	CO_2 respiration, O_2 uptake
Heat Drying	Moisture content
Alkaline Stabilization	pH; pH change with storage; moisture; ammonia evolution; temperature
Aerobic Digestion	SOUR; volatile solids reduction, additional volatile solids reduction
Anaerobic Digestion	Gas production; volatile solids reduction, additional volatile solids reduction

More information on stability can be found in the WERF publication, “Defining Biosolids Stability: A Basis for Public and Regulatory Acceptance” (1997).

The Part 503 regulation contains 12 options, described below and summarized in Table 8-2, for demonstrating a reduction in vector attraction of sewage sludge. These requirements are designed to either reduce the attractiveness of sewage sludge to vectors (Options 1 through 8 and Option 12) or prevent the vectors from coming in contact with the sewage sludge (Options 9 through 11).

Guidance on when and where to sample sewage sludge to meet these requirements is provided in Chapter 10.

As mentioned in Chapter 3, meeting the vector attraction reduction requirements must be demonstrated separately from meeting the pathogen reduction requirements. Therefore, demonstration of vector attraction reduction (e.g., through reduction of volatile solids by 38% as described below) does not demonstrate achievement of pathogen reduction. It should be noted that for Class A biosolids, vector attraction reduction must be met after or concurrent with pathogen reduction to prevent growth of pathogenic bacteria.

8.2 Option 1: Reduction in Volatile Solids Content [503.33(b)(1)]

This option is intended for use with biological treatment systems only. Under Option 1, reduction of vector attraction is achieved if the mass of volatile solids in the sewage sludge is reduced by at least 38%. This is the percentage

Table 8-2. Vector Attraction Reduction Options

Requirement	What is Required?	Most Appropriate For:
Option 1 503.33(b)(1)	At least 38% reduction in volatile solids during sewage sludge treatment	Sewage sludge processed by: Anaerobic biological treatment Aerobic biological treatment
Option 2 503.33(b)(2)	Less than 17% additional volatile solids loss during bench-scale anaerobic batch digestion of the sewage sludge for 40 additional days at 30°C to 37°C (86°F to 99°F)	Only for anaerobically digested sewage sludge that cannot meet the requirements of Option 1
Option 3 503.33(b)(3)	Less than 15% additional volatile solids reduction during bench-scale aerobic batch digestion for 30 additional days at 20°C (68°F)	Only for aerobically digested liquid sewage sludge with 2% or less solids that cannot meet the requirements of Option 1 — e.g., sewage sludges treated in extended aeration plants. Sludges with 2% solids must be diluted
Option 4 503.33(b)(4)	SOUR at 20°C (68°F) is ≤1.5 mg oxygen/hr/g total sewage sludge solids	Liquid sewage sludges from aerobic processes run at temperatures between 10 to 30°C. (should not be used for composted sewage sludges)
Option 5 503.33(b)(5)	Aerobic treatment of the sewage sludge for at least 14 days at over 40°C (104°F) with an average temperature of over 45°C (113°F)	Composted sewage sludge (Options 3 and 4 are likely to be easier to meet for sewage sludges from other aerobic processes)
Option 6 503.33(b)(6)	Addition of sufficient alkali to raise the pH to at least 12 at 25°C (77°F) and maintain a pH ≥12 for 2 hours and a pH≥11.5 for 22 more hours	Alkali-treated sewage sludge (alkaline materials include lime, fly ash, kiln dust, and wood ash)
Option 7 503.33(b)(7)	Percent solids ≥ 75% prior to mixing with other materials	Sewage sludges treated by an aerobic or anaerobic process (i.e., sewage sludges that do not contain unstabilized solids generated in primary wastewater treatment)
Option 8 503.33(b)(8)	Percent solids ≥90% prior to mixing with other materials	Sewage sludges that contain unstabilized solids generated in primary wastewater treatment (e.g., heat-dried sewage sludges)
Option 9 503.33(b)(9)	Sewage sludge is injected into soil so that no significant amount of sewage sludge is present on the land surface 1 hour after injection, except Class A sewage sludge which must be injected within 8 hours after the pathogen reduction process	Sewage sludge applied to the land or placed on a surface disposal site. Domestic septage applied to agricultural land, a forest, or a reclamation site, or placed on a surface disposal site
Option 10 503.33(b)(10)	Sewage sludge is incorporated into the soil within 6 hours after application to land or placement on a surface disposal site, except Class A sewage sludge which must be applied to or placed on the land surface within 8 hours after the pathogen reduction process	Sewage sludge applied to the land or placed on a surface disposal site. Domestic septage applied to agricultural land, forest, or a reclamation site, or placed on a surface disposal site
Option 11 503.33(b)(11)	Sewage sludge placed on a surface disposal site must be covered with soil or other material at the end of each operating day	Sewage sludge or domestic septage placed on a surface disposal site
Option 12 503.33(b)(12)	pH of domestic septage must be raised to ≥12 at 25°C (77°F) by alkali addition and maintained ≥ 12 for 30 minutes without adding more alkali	Domestic septage applied to agricultural land, a forest, or a reclamation site or placed on a surface disposal site

of volatile solids reduction that can generally be attained by the "good practice" recommended conditions for anaerobic digestion of 15 days residence time at 35°C [95°F] in a completely mixed high-rate digester. The percent volatile solids reduction can include any additional volatile solids reduction that occurs before the biosolids leave the treatment works, such as might occur when the sewage sludge is processed on drying beds or in lagoons.

The starting point for measuring volatile solids in sewage sludge is at the point at which sewage sludge enters a sewage sludge treatment process. This can be problem-

atic for facilities in which wastewater is treated in systems like oxidation ditches or by extended aeration. Sewage sludges generated in these processes are already substantially reduced in volatile solids content by their long exposure to oxidizing conditions in the process. If sewage sludge removed from these processes is further treated by anaerobic or aerobic digestion to meet VAR requirements, it is unlikely that the 38% reduction required to meet Option 1 can be met. In these cases, use of Options 2, 3, or 4 is more appropriate.

The end point where volatile solids are measured to calculate volatile solids losses can be at any point in the process. Because volatile solids continue to degrade throughout sewage sludge treatment, it is recommended that samples be taken at the end point of treatment.

Volatile solids reduction is calculated by a volatile solids balance around the digester or by the Van Kleeck formula (Fisher, 1984). Guidance on methods of calculation is provided in Appendix C.

Volatile solids reduction is typically achieved by anaerobic or aerobic digestion. These processes degrade most of the biodegradable material to lower activity forms. Any biodegradable material that remains characteristically degrades so slowly that vectors are not drawn to it.

8.3 Option 2: Additional Digestion of Anaerobically Digested Sewage Sludge [503.33(b)(2)]

Under this option, an *anaerobically* digested sewage sludge is considered to have achieved satisfactory vector attraction reduction if it loses less than 17% additional volatile solids when it is anaerobically batch-digested in the laboratory in a bench-scale unit at 30°C to 37°C (86°F to 99°F) for an additional 40 days. Procedures for this test are presented in Appendix D. As noted in Appendix D, the material balance method for calculating additional volatile solids reduction will likely show greater reductions than the Van Kleeck method.

Frequently, return activated sludges have been recycled through the biological wastewater treatment section of a treatment works or have resided for long periods of time in the wastewater collection system. During this time they undergo substantial biological degradation. If they are subsequently treated by anaerobic digestion for a period of time, they are adequately reduced in vector attraction, but because they entered the digester with volatile solids already partially reduced, the volatile solids reduction after treatment is frequently less than 38%. The additional digestion test is used to demonstrate that these sewage sludges are indeed satisfactorily reduced in vector attraction.

It is not necessary to demonstrate that Option 1 cannot be met before using Option 2 or 3 to comply with VAR requirements.

This additional anaerobic digestion test may have utility beyond use for sewage sludge from the classical anaerobic digestion process. The regulation states that the test can be used for a previously anaerobically digested sewage sludge. One possible application is for sewage sludge that is to be removed from a wastewater lagoon. Such sewage sludge may have been stored in such a lagoon for many years, during which time it has undergone anaerobic digestion and lost most of its volatile solids. It is only recognized by the regulations as a sewage sludge when it is removed from the lagoon. If it were to be further processed by anaerobic digestion, the likelihood of achieving 38% volatile solids reduction is very low. The additional anaerobic digestion test which requires a long period of batch digestion at temperatures between 30°C and 37°C would seem to be an appropriate test to determine whether such a sewage sludge has the potential to attract vectors.

8.4 Option 3: Additional Digestion of Aerobically Digested Sewage Sludge [503.33(b)(3)]

Under this option, an *aerobically* digested sewage sludge with 2% or less solids is considered to have achieved satisfactory vector attraction reduction if it loses less than 15% additional volatile solids when it is aerobically batch-digested in the laboratory in a bench-scale unit at 20°C (68°F) for an additional 30 days. Procedures for this test and the method for calculating additional volatile solids destruction are presented in Appendix D. The test can be run on sewage sludges up to 2% solids and does not require a temperature correction for sewage sludges not initially digested at 20°C (68°F). Liquid sludges with greater than 2% solids can be diluted to 2% solids with unchlorinated effluent, and the test can then be run on the diluted sludge. This option should not be used for non-liquid sewage sludge such as dewatered cake or compost.

This option is appropriate for aerobically digested sewage sludges that cannot meet the 38% volatile solids reduction required by Option 1. These include sewage sludges from extended aeration and oxidation ditch processes, where the nominal residence time of sewage sludge leaving the wastewater treatment processes section generally exceeds 20 days. In these cases, the sewage sludge may already have been substantially reduced in biological degradability prior to aerobic digestion.

As was suggested for the additional anaerobic digestion test, the additional aerobic digestion test may have application to sewage sludges that have been aerobically treated by other means than classical aerobic digestion.

8.5 Option 4: Specific Oxygen Uptake Rate (SOUR) for Aerobically Digested Sewage Sludge [503.33(b)(4)]

For an aerobically digested sewage sludge with a total solids content equal to or less than 2% which has been processed at a temperature between 10°- 30°C, reduction in vector attraction can also be demonstrated using the SOUR test. The SOUR of the sewage sludge to be used or disposed must be less than or equal to 1.5 mg of

oxygen per hour per gram of total sewage sludge solids (dry weight basis) at 20°C (68°F).[1] This test is based on the fact that if the aerobically treated sewage sludge consumes very little oxygen, its value as a food source for vectors is very low and therefore vectors are unlikely to be attracted to it. Frequently aerobically digested sewage sludges are circulated through the aerobic biological wastewater treatment process for as long as 30 days. In these cases, the sewage sludge entering the aerobic digester is already partially digested, which makes it difficult to demonstrate the 38% reduction required by Option 1.

The oxygen uptake rate depends on the conditions of the test and, to some degree, on the nature of the original sewage sludge before aerobic treatment. The SOUR test should not be used on sewage sludge products such as heat or air dried sludge or compost. Because of the reduction of microbial populations that occur in these processes, the SOUR results are not accurate and should not be used. SOUR testing on sewage sludges with a total solids content below 0.5% may give inaccurately high results. Farrell, et al. (1996) cite the work of several investigators indicating such an effect. Farrell, et al. (1996) also note that storage for up to two hours did not cause a significant change in the SOUR measurement. It is therefore suggested that a dilute sewage sludge could be thickened to a solids content less than 2% solids and then tested, provided that the thickening period is not in excess of two hours.

The SOUR test requires a poorly defined temperature correction at temperatures differing substantially from 20°C (68°F). SOUR cannot be applied to sewage sludges digested outside the 10-30°C range (50-86°F). The actual temperature of the sewage sludge tested cannot be adjusted because temperature changes can cause short-term instability in the oxygen uptake rate (Benedict, et al. (1973); Farrell, et al. [1996]), and this would invalidate the results of the test. Guidance on performing the SOUR test and on sewage sludge-dependent factors are provided in Appendix D.

It should be noted that the limit on the use of the SOUR test for sewage sludges at different solids and temperature levels is due to the lack of research and data on different sewage sludges. EPA encourages the collection of SOUR data for different sewage sludges so that at some point, Option 4 may be expanded to include more sewage sludge materials.

[1] SOUR is defined in Part 503 as the mass of oxygen consumed per unit time per unit mass of total solids (dry weight basis) in the sewage sludge. SOUR is usually based on total suspended volatile solids rather than total solids because it is assumed that it is the volatile matter in the sewage sludge that is being oxidized. The SOUR definition in Part 503 is based on the total solids primarily to reduce the number of different determinations needed and for consistency with application rates, which are measured in total solids per unit area. Generally, the range in the ratio of volatile solids to total solids in aerobically digested sewage sludges is not large. The SOUR based on total solids will merely be slightly lower than if it had been based on volatile suspended solids to indicate the same endpoint.

8.6 Option 5: Aerobic Processes at Greater Than 40°C [503.33(b)(5)]

The sewage sludge must be aerobically treated for 14 days or longer during which time the temperature must be over 40°C (104°F) and the average temperature higher than 45°C (113°F). This option applies primarily, but not exclusively, to composted sewage sludge. These processed sewage sludges generally contain substantial amounts of partially decomposed organic bulking agents, in addition to sewage sludge. This option must be used for composted sewage sludge; other options are either not appropriate or have not adequately been investigated for use with compost.

The Part 503 regulation does not specifically mention or limit this option to composting. This option can be applied to sewage sludge from other aerobic processes such as aerobic digestion as long as temperature requirements can be met and the sewage sludge is maintained in an aerobic state for the treatment period, but other methods such as Options 3 and 4 are likely to be easier to meet for these sewage sludges.

If composting is used to comply with Class A pathogen requirements, the VAR time-temperature regime must be met along with or after compliance with the pathogen reduction time-temperature regime.

8.7 Option 6: Addition of Alkali [503.33(b)(6)]

Sewage sludge is considered to have undergone adequate vector attraction reduction if sufficient alkali is added to:

- Raise the pH to at least 12
- Maintain a pH of at least 12 without addition of more alkali for 2 hours
- Maintain a pH of at least 11.5 without addition of more alkali for an additional 22 hours

pH should be measured in a slurry at 25°C. For more information on making a slurry, see Section 10.7. Either sewage sludge samples may be taken and heated or cooled to 25°C or results can be adjusted based on the ambient temperature where pH is measured and the following calculation:

$$\text{Correction Factor} = \frac{0.03 \text{ pH units} \times (T_{meas} - 25°C)}{1.0°C}$$

Actual pH = Measured pH +/- the Correction Factor

T = Temperature measured

Example of Using the pH Correction Factor

If the measured pH is 12.304 at 30°C, the actual pH can be calculated as follows:

Correction Factor = 0.03 x (30-25) = +0.15
Actual pH = 12.304 + 0.15 = 12.454

It should be noted that temperature compensation devices on pH meters correct only for variations in the conductance of pH probes, and not for the variability in solution concentration. Therefore, the temperature correction noted above should be applied to pH measurements, even if a pH meter with temperature settings is used.

As noted in Section 5.6, the term "alkali" means a substance that causes an increase in pH. Raising sewage sludge pH through alkali addition reduces vector attraction by reducing or stopping biological activity. However, this reduction in biological activity is not permanent. If the pH drops, surviving bacteria become biologically active and the sewage sludge will again putrefy and potentially attract vectors. The more soluble the alkali, the less likely it is that there will be an excess present when a pH of 12 is reached. Consequently, the subsequent drop in pH with time will be more rapid than if a less soluble alkali is used.

The conditions required under this option are designed to ensure that the sewage sludge can be stored for at least several days at the treatment works, transported, and applied to soil without the pH falling to the point where biological activity results in vector attraction. The requirement of raising the pH to 12 increases the probability that the material will be used before pH drops to a level at which putrefaction can occur. The requirements for pH adjustment of domestic septage are less stringent because it is unlikely that septage haulers will hold domestic septage for long periods of time.

Raising the pH to 12 and maintaining this pH for two hours and a pH of 11.5 for an additional 22 hours ensures that the pH will stay at adequately high levels to prevent putrefaction before disposal in all but unusual cases. In any event, it is prudent in a timely manner to apply sludge in a thin layer or incorporate it into the soil for the prevention of odors and vector attraction.

More information on alkali addition and measurement of pH are included in Chapter 10.

8.8 Option 7: Moisture Reduction of Sewage Sludge Containing No Unstabilized Solids [503.33(b)(7)]

Under this option, vector attraction is considered to be reduced if the sewage sludge does not contain unstabilized solids generated during primary wastewater treatment and if the solids content of the sewage sludge is at least 75% before the sewage sludge is mixed with other materials. Thus, the reduction must be achieved by removing water, not by adding inert materials.

It is important that the sewage sludge not contain unstabilized solids because the partially degraded food scraps likely to be present in such a sewage sludge could attract birds, some mammals, and possibly insects, even if the solids content of the sewage sludge exceeds 75%.

The way dried sewage sludge is handled or stored before use or disposal can create or prevent vector attraction. If dried sewage sludge is exposed to high humidity, the outer surface of the sewage sludge could equilibrate to a lower solids content and attract vectors. Proper management should be conducted to prevent this from happening.

8.9 Option 8: Moisture Reduction of Sewage Sludge Containing Unstabilized Solids [503.33(b)(8)]

Vector attraction of any sewage sludge is considered to be reduced if the solids content of the sewage sludge is increased to 90% or greater. This extreme desiccation deters vectors in all but the most unusual situations. As noted for Option 7, the solids increase should be achieved by removal of water and not by dilution with inert solids. Drying to this extent severely limits biological activity and strips off or decomposes the volatile compounds that attract vectors.

Because sewage sludge meeting vector attraction reduction with this option may contain unstabilized solids, material that absorbs moisture or is rewet may putrefy and attract vectors. Proper storage and use of this material should be considered in order to prevent potential pathogen growth and vector attraction.

8.10 Option 9: Injection [503.33(b)(9)]

Vector attraction reduction can be achieved by injecting the sewage sludge below the ground. Under this option, no significant amount of the sewage sludge can be present on the land surface within 1 hour after injection, and, if the sewage sludge is Class A with respect to pathogens, it must be injected within 8 hours after discharge from the pathogen-reduction process.

Injection of sewage sludge beneath the soil places a barrier of earth between the sewage sludge and vectors. The soil quickly removes water from the sewage sludge, which reduces the mobility and odor of the sewage sludge. Odor is usually present at the site during the injection process, but it quickly dissipates when injection is complete.

The special restriction requiring injection within 8 hours for Class A sewage sludge is needed because these sewage sludges are likely devoid of actively growing bacteria and are thus an ideal medium for growth of pathogenic bacteria (see Section 4.3). If pathogenic bacteria are present (survivors or introduced by contamination), their numbers increase slowly for the first 8 hours after treatment, but after this period, their numbers can rapidly increase. This kind of explosive growth is not likely to happen with Class B sludge because high densities of nonpathogenic bacteria are present which suppresses the growth of pathogenic bacteria. In addition, the use of Class B biosolids requires site restrictions which reduce the risk of public exposure to pathogens. Consequently, this special requirement is not needed for Class B biosolids

8.11 Option 10: Incorporation of Sewage Sludge into the Soil [503.33(b)(10)]

Under this option, sewage sludge applied to the land surface or placed on a surface disposal site must be incorporated into the soil within 6 hours after application to or placement on the land. If the sewage sludge is Class A with respect to pathogens, the time between processing and incorporation after application or placement must not exceed 8 hours -- the same as for injection under Option 9.

When applied at agronomic rates, the loading of sewage sludge solids typically is about 1/100th or less of the mass of soil in the plow layer (approximately the top six inches of soil). If mixing is reasonably good, the dilution of sewage sludge in the soil surface is equivalent to that achieved with soil injection. Odor will be present and vectors will be attracted temporarily, as the sewage sludge dewaters on the soil surface. This attraction diminishes and is virtually eliminated when the sewage sludge is mixed with the soil. The mixing method applies to liquid sewage sludges, dewatered sewage sludge cake, and even to dry sewage sludges that have not already met the vector attraction reduction requirements of the regulation by one of the other options.

The 6 hours allowed to complete the mixing of sewage sludge into the soil should be adequate to allow for proper incorporation. As a practical matter, it may be wise to complete the incorporation in a much shorter time. Clay soils tend to become unmanageably slippery and muddy if the liquid sewage sludge is allowed to soak into the first inch or two of topsoil.

8.12 Option 11: Covering Sewage Sludge [503.33(b)(11)]

Under this option, sewage sludge placed on a surface disposal site must be covered with soil or other material at the end of each operating day. Daily covering reduces vector attraction by creating a physical barrier between the sewage sludge and vectors, while environmental factors work to reduce pathogens.

8.13 Option 12: Raising the pH of Domestic Septage [503.33(b)(12)]

This option applies only to domestic septage applied to agricultural land, forest, a reclamation site, or surface disposal site. Vector attraction is reduced if the pH is raised to at least 12 through alkali addition and maintained at 12 or higher for 30 minutes without adding more alkali. (These conditions also accomplish pathogen reduction for domestic septage--see Section 5.6.) When this option is used, every container (truckload) must be monitored to demonstrate that it meets the requirement. As noted in Section 5.6, “alkali” refers to a substance that causes an increase in pH.

This vector attraction reduction requirement is slightly less stringent than the alkali addition requirement for sewage sludge. The method is geared to the practicalities of the use or disposal of domestic septage, which is typically treated by lime addition in the domestic septage hauling truck. The treated septage is typically applied to the land shortly after lime addition. During the very short time interval, the pH is unlikely to fall to a level at which vector attraction could occur.

If domestic septage is not applied soon after pH adjustment, it is recommended that pH be retested, and additional alkali be added to the domestic septage to raise the pH to 12 if necessary. Alternatively, if pH has dropped and the domestic septage begins to putrefy, it is advisable to cover or incorporate the domestic septage in order to prevent vector attraction.

8.14 Number of Samples and Timing

Unlike pathogenic bacteria, volatile solids cannot regenerate once they are destroyed, so samples can be taken at any point along the process. However, since volatile solids are destroyed throughout treatment, it is recommended that samples be taken at the end of processing.

Facilities which use Option 2 or 3 to demonstrate vector attraction reduction must schedule sampling to leave ample time to complete the laboratory tests before sewage sludge is used or disposed. A suggested procedure would be to take several samples at evenly spaced time intervals during the period between the required monitoring dates and calculate running averages comprised of at least four volatile solids results. This has the advantage of not basing the judgement that the process is performing adequately (or inadequately) on one or two measurements that could be erroneous because of experimental error or a poorly chosen sample inadvertently taken during a brief process upset. It also provides an important quality control measure for process operations. Since the Part 503 regulations do not specify a sampling program, it is recommended that sewage sludge preparers consult with the regulatory authority with regard to sampling schedules.

8.15 Vector Attraction Reduction Equivalency

Many of the vector attraction reduction tests are time consuming and inconvenient, particularly for small treatment plants that do not have a laboratory. Efforts to define new, simpler methods for measuring vector attraction are on-going.

Since it is infeasible to measure the actual attraction of vectors, given the large number of variables, methodology development must continue to focus on the cause of vector attraction, namely the availability of a food source (volatile solids) or odor. The tests to measure the attractants may vary depending on the technology by which the sewage sludge is processed.

Some of the parameters which might be used to measure vector attraction may include gas production or measures of microbial activity. For example, several methods

which measure carbon dioxide evolution or reheating potential are currently in use to measure compost stability, but these methods must be examined more closely to determine if they can be applied to other forms of sewage sludge and if results can be adequately correlated to vector attraction.

The responsibility to eventually develop additional vector attraction reduction test protocols lies with the scientific community and the sewage sludge industry. Since there is currently no standard procedure for considering VAR equivalency, new methods must be submitted to the EPA for consideration and potential inclusion in the next rulemaking effort.

Chapter 9
Sampling Procedures and Analytical Methods

9.1 Introduction

Many of the Part 503 Subpart D pathogen and vector attraction reduction requirements call for monitoring and analysis of the sewage sludge to ensure that microbiological quality and vector attraction reduction meet specified requirements (see Chapters 4 to 6 for a description of the requirements).The purpose of this chapter is to describe procedures for obtaining representative samples and ensuring their quality and integrity. It also summarizes the analytical methods required under Part 503, and directs the reader to other sections of this document that describe some of those methods.

Sampling personnel will also benefit from reading expanded presentations on the subject. “Standard Methods” (APHA, 1992), “Principles of Environmental Sampling” (Keith, 1988), “Samplers and Sampling Procedures for Hazardous Waste Streams” (EPA, 1980), "Sludge Sampling and Analysis Guidance Document” (EPA, 1993) and ASTM Standard E 300-86, “Standard Practice for Sampling Industrial Chemicals” (ASTM, 1992a) are highly recommended. The latter publication provides an in-depth description of available sampling devices and procedures.

When referring to other publications, it is important to note that most guidance on specific sampling techniques is directed toward chemical analysis. Procedures described may be inappropriate for microbiological sampling because they expose the samples to possible contamination, or may be appropriate only after some modification to reduce the risk of microbial contamination during sampling.

9.2 Laboratory Selection

A very important, but often overlooked component of pathogen and vector attraction monitoring is selecting an appropriate analytical laboratory. The analysis of sewage sludge or biosolids for indicator and pathogenic organisms is more complex than water analysis. Solid samples such as biosolids are prepared differently than water samples and also typically contain a much higher background microbial population than water contains. Biosolids products such as compost can be very heterogeneous, requiring special sample preparation procedures. It is therefore important to use a laboratory that has developed an expertise through the routine analysis of biosolids products. Regional and state sludge coordinators should be contacted for assistance in selecting a qualified laboratory.

To ensure that a laboratory has adequate experience with biosolids analyses, the following information should be obtained and reviewed.

- For how long has the laboratory been analyzing biosolids for the specified parameters?
- Approximately how many biosolids samples does the laboratory analyze per week or month?
- For how many wastewater treatment facilities is the laboratory conducting the specified analyses?
- A list of references.
- Does the laboratory have a separate and distinct microbiology lab?
- Does the laboratory have microbiologists on staff? Request and review their resumes.
- Who will actually perform the analyses?
- Is the laboratory familiar with the analytical procedures including sample preparation, holding times, and QA/QC protocols?

A laboratory tour and reference check are also recommended. A good laboratory should be responsive, providing requested technical information in a timely manner. It is the biosolids generator’s responsibility to provide accurate analytical results. Consequently, the selection of an appropriate laboratory is an important component of developing a biosolids monitoring plan.

9.3 Safety Precautions

Sewage sludges that are being sampled should be presumed to contain pathogenic organisms, and should be handled appropriately. Both the sampler and the person carrying out the microbiological analysis must take appropriate precautions. Safety precautions that should be taken when sampling and when analyzing the samples are discussed in Standard Methods (APHA, 1992) in Sections 1060A and 1090C.

Individuals performing sampling (usually employees of wastewater treatment works) should receive training in the microbiological hazards of sewage sludge and in safety

precautions to take when sampling. Laboratory personnel should be aware that the outside of every sample container is probably contaminated with microorganisms, some of which may be pathogens. Personal hygiene and laboratory cleanliness are also extremely important. Several safety practices that should be standard procedures during sample collection and analysis are:

- Gloves should be worn when handling or sampling untreated sewage sludge or treated biosolids.
- Personnel taking the samples should clean sample containers, gloves, and hands before delivering the samples to others.
- Hands should be washed frequently and always before eating, smoking, and other activities that involve hand-to-mouth contact.
- Photocell-activated or foot-activated hand washing stations are desirable to reduced spreading of contamination to others.
- Employees should train themselves to avoid touching their lips or eyes.
- Mouth pipetting should be forbidden.
- Smoking should not be allowed inside the lab.

Employees involved in sample collection (or any other activity where they are exposed to wastewater or sewage sludges) should review their immunization history. At a minimum, employees should be immunized against tetanus. However, employees should consider immunization for other diseases, particularly hepatitis A and B. Employees should also consider having a blood sample analyzed to determine if they still have active antibodies for the various immunizations they received as children.

Personnel analyzing sewage sludge or biosolids samples should receive training in awareness and safety concerning biohazards. Because microbiological laboratories have safety programs, this subject is not covered in depth here. A facility's sampling plan should include a section on microbiological hazards and appropriate safety practices or, alternatively, refer the reader to another document where this information is presented.

9.4 Requirements for Sampling Equipment and Containers

Containers

Sampling containers may be of glass or plastic that does not contain a plasticizer (Teflon, polypropylene, and polyethylene are acceptable). Plastic bags are especially useful for thick sewage sludges and free-flowing solids. Presterilized bags are available. Stainless steel containers are acceptable, but steel or zinc coated steel vessels are not appropriate. In addition to providing guidance on appropriate containers for specific analyses, private analytical laboratories will typically provide sample containers at no cost. Sampling containers used for microbiological analyses should be sterile. Sampling tools that come in contact with the actual sample should be constructed of stainless steel, which is easily cleaned, and sterilized. Tools made of wood, which is difficult to sterilize because of porosity, should not be used.

Equipment

The sampling equipment used is primarily dependent on the type of material being sampled. For relatively high solids content biosolids, a hand trowel or scoop may be adequate, whereas, collecting stratified samples from a lagoon requires more sophisticated and specialized equipment. Automated sampling equipment, as commonly used for wastewater, should not be used. Such equipment can cause solids separation during sampling and is difficult to clean, resulting in cross contamination. Sampling equipment should be constructed of non-corrosive materials, such as stainless steel, Teflon, or glass, that can be thoroughly cleaned. Sampling equipment should be dedicated for this task and should not be used for other applications. Equipment should be cleaned well with detergent and a nylon scrub brush after each use and stored inside in a dedicated location. The types of sampling equipment and their applications are presented in Table 9-1. The use of this equipment is discussed in greater detail in Sections 9.6 and 9.7.

Sterilization

The containers and tools used for sampling must be sterilized if the biosolids product is to be analyzed for Class A microbiological parameters. Alternatively, pre-sterilized, disposable scoops, and other sampling devices can be purchased, alleviating the need to sterilize sampling equipment. Conservative microbiological practice also requires sterilization of containers and sampling tools used for collecting samples to be tested for meeting the Class B requirements. Sample containers and equipment should be scrupulously cleaned prior to actual sample collection. After the samples are collected, the sampling equipment should be cleaned well with soap and water and put away until the next sampling event. Equipment should be dedicated to sampling and not used for other activities. Only equipment that touches the actual sample must be sterilized. Equipment such as shovels or heavy equipment used to access a sludge pile interior does not need to be sterilized, but should be clean, as long as another sterile sample collection device (such as a hand trowel) is used to access and collect the actual sample. Sterilization is not required when collecting samples of sewage sludge to be used in vector attraction reduction tests, but all equipment must be clean.

Either steam or a sterilizing solution such as sodium hypochlorite (household bleach) should be used for sterilizing equipment. If bleach is used, equipment must be rinsed thoroughly in order to prevent residual bleach from having an effect on the microbial population in the sample. Equipment should be thoroughly washed with water, soap, and a brush prior to sterilization. If an autoclave or large

Table 9-1. Equipment Used for Collecting Sewage Sludge Samples

Equipment	Application
Composite Liquid Waste Sampler (Coliwasa)	The Coliwasa is a device employed to sample free-flowing sewage sludges contained in drums, shallow tanks, pits, and similar containers. It is especially useful for sampling wastes that consist of several immiscible liquid phases. The Coliwasa consists of a glass, plastic, or metal tube equipped with an end closure that can be opened and closed while the tube is submerged in the material to be sampled.
Weighted Bottle	This sampling device consists of a glass or plastic bottle, sinker, stopper, and a line that is used to lower, raise, and open the bottle. The weighted bottle is used for sampling free flowing sewage sludges and is particularly useful for obtaining samples at different depths in a lagoon. A weighted bottle with line is built to the specifications in ASTM Method D270 and E300.
Dipper	The dipper consists of a glass or plastic beaker clamped to the end of a two- or three-piece telescoping aluminum or fiberglass pole that serves as the handle. A dipper is used for obtaining samples of free flowing sewage sludges that are difficult to access. Dippers are not available commercially and must be fabricated.
Sampling Thief	A thief consists of two slotted concentric tubes, usually made of stainless steel or brass. The outer tube has a conical pointed tip that permits the sampler to penetrate the material being sampled. The inner tube is rotated to open and close the sampler. A thief is used to sample high solids content materials such as composted and heat dried biosolids for which particle diameter is less than one-third the width of the slots. Thief samplers are available from laboratory supply companies.
Trier	A trier consists of a tube cut in half lengthwise with a sharpened tip that allows the sampler to cut into sticky materials such as dewatered cake and lime stabilized biosolids. A trier samples moist or sticky solids with a particle diameter less than one-half the diameter of the trier. Triers 61 to 100 cm long and 1.27 to 2.54 cm in diameter are available from laboratory supply companies
Auger	An auger consists of sharpened spiral blades attached to a hard metal central shaft. An auger can be used to obtain samples through a cross section of a biosolids stockpile. Augers are available at hardware and laboratory supply stores.
Scoops and Shovels	Scoops are used to collect samples from sewage sludge or biosolids stockpiles, shallow containers, and conveyor belts. Stainless steel or disposable plastic scoops are available at laboratory supply houses. Due to the difficulty of sterilizing shovels and other large sampling equipment, this type of equipment should only be used for accessing the center of stockpiles and should not be used for collecting the actual sample.

pressure cooker is available, enclose the sampling tool in a kraft paper bag and place the bag in the autoclave. A minimum period of 30 minutes at a temperature of 121°C is required for sterilization. The kraft paper bag keeps the sampling device from becoming contaminated in the field. A steam cleaner can also be used to sterilize sampling equipment. Place the equipment in a heat resistant plastic bucket and direct steam onto the equipment for a minimum of 10 minutes. When done, place the sterilized equipment in a kraft paper bag.

Many facilities do not have an autoclave or steam cleaning equipment and will need to use a sterilizing solution to sterilize equipment. A 10% household bleach solution (1 part bleach, 9 parts water) is readily available and works well. However, bleach is corrosive and may also affect the microbial population of a sample and does need to be adequately removed from the equipment prior to sample collection. Make up the 10% solution in a clean plastic bucket. Immerse each piece of clean equipment in the solution for a minimum contact time of a minute. Rinse the equipment in another bucket containing sterile or boiled water. Let the equipment air dry for a few minutes or dry with sterile paper or cloth towels. After drying, place the equipment in a paper bag. Sterile plastic bags obtained from a scientific equipment supplier can also be used for short-term sterile equipment storage.

9.5 Sampling Frequency and Number of Samples Collected

The primary objective of biosolids monitoring is to assure that all of the biosolids produced meet the regulatory requirements related to land application. It is obviously not feasible to sample and analyze every load of biosolids leaving a facility, nor is it necessary. However, a sampling plan does need to adequately account for the variability of the biosolids. This entails collecting samples at an adequate frequency and analyzing a sufficient number of samples. The minimum sampling frequency and number of samples to be analyzed are shown in 40 CFR Part 503. As shown in Table 3-4, the sample collection frequency is determined by the amount of biosolids used or disposed.

The number of samples which must be analyzed for compliance with Class A microbiological parameters is not specified, however, it is strongly recommended that multiple samples per sampling event be analyzed for biosolids. The number of samples taken must be sufficient to adequately represent biosolids quality. It must be noted that for Class A biosolids, analytical results are not averaged: every sample analyzed must meet the Class A requirements.: “Either the density of fecal coliform in the sewage sludge must be less than 1,000 MPN per gram of total solids (dry weight basis), or the density of *Salmonella* sp.

bacteria in sewage sludge must be less than 3 MPN per 4 grams of total solids (dry weight basis)."

To meet Class B Alternative 1 requirements, seven samples must be taken and the geometric mean of results must meet the 2.0×10^6 MPN fecal coliform per dry gram limit (see Chapter 5). It is recommended that the samples be taken over a two-week period in order to adequately represent variability in the sewage sludge.

The actual sampling and analysis protocol is typically developed by the facility and reported to the regulatory authority, which can require a more stringent sampling and analysis protocol than that stipulated in the Part 503 regulation. In some cases, the regulatory authority may initially require a more stringent monitoring schedule which may be relaxed once product consistency is established. The biosolids preparer should carefully consider the treatment process, analytical variability, end-use, and other factors when determining the frequency and number of samples to be analyzed. Collecting samples more frequently or analyzing more samples will help to ensure the product meets the regulatory criteria and that pathogen and vector attraction reduction goals have been met. More information on this subject is available in Chapter 10.

It is recommended that additional sampling be conducted for heterogeneous biosolids products. A single grab sample may adequately represent the sewage sludge in a digester that is being mixed, but might not adequately represent several hundred yards of compost product stored in several stockpiles. Likewise, a facility that conducts a single annual analysis should consider more frequent monitoring, particularly if the analytical results from the annual analysis are near the regulatory limit. It is a facility's responsibility and in the facility's best interest to develop a monitoring plan that assures product quality.

9.6 Sampling Free-Flowing Sewage Sludges

Sewage sludges below about 7% solids behave, at worst, like moderately viscous liquids such as an SAE 20 lubricating oil. They flow freely under small pressure gradients, and flow readily into a sample bottle. They are heterogeneous, and concentration gradients develop upon standing. Generally settling is slow and is overcome by good mixing.

Liquid sewage sludges may be flowing in pipes, undergoing processing, or stored in concrete or metal tanks, in tank cars or tank trucks, or in lagoons. This section describes procedures for sampling from these various situations, except for lagoons, which are discussed in Section 9.7.

Filling Containers

Liquid sewage sludge samples are usually transferred into wide mouth bottles or flexible plastic containers. Sewage sludges can generate gases, and pressure may build up in the container. Consequently, the bottle or container is generally not filled. If the sewage sludge is to be used for the oxygen uptake test, the sample bottle should not be more than half full, to provide some oxygen for respiration of the microorganisms in the sewage sludge. Conversely, if the sewage sludge is to be used for the additional anaerobic digestion test for vector attraction reduction, it is important that it not be exposed to oxygen more than momentarily. Consequently, sample bottles must be completely filled to the top. Bottles should have closures that can pop off, or else be made of flexible plastic that can both stretch and assume a spherical shape to relieve any internal pressure that develops.

The containers used to collect the samples can be widemouth bottles that can be capped, or pails. If a pail is used and only part of its contents will be taken as a sample, the sample should be transferred to a bottle at the sampling location. Preferably, the transfer should be made by use of a ladle rather than by pouring, since some settling can occur in the pail, particularly with primary or mixed sewage sludges of solids contents below about 3%.

Collecting Liquid Sewage Sludge Samples

If liquid sewage sludges are to be sampled, it is most desirable to sample them as they are being transferred from one vessel to another. Preferably this is done downstream of a pump that serves to mix the sewage sludge thoroughly. Ideally, the sample is taken through a probe facing upstream in the center of the discharge pipe and is withdrawn at the velocity of the liquid at the center-line of the pipe. This approach generally is not possible with sewage sludge, because fibrous deposits can build up on the probe and plug up the pipeline.

Sampling through a side tap off the main discharge pipe is adequate only if the flow is turbulent and the sample point is over ten pipe diameters downstream from the pipe inlet (e.g., for a 3-inch [7.6-cm] pipe, 30 inches [76 cm] downstream) or the tap is downstream from a pump. For any kind of a slurry, the fluid at the wall contains fewer particles than the bulk of the fluid in the pipe. The sample should be withdrawn fast enough so that it minimizes the amount of thinned-out fluid from the outside pipe wall that enters the sample.

If the sewage sludge discharges into the open as it is transferred from one vessel to another, it can be sampled by passing a sample container through the discharge. The container should be large enough to catch the whole discharge during the sampling interval, rather than, for example, just sampling the center or the edge of the discharge. The sample container could be a pail or a beaker at the end of an extension arm. Sample volume should be about three times what is needed for the analyses planned.

The collection of a representative sample often requires the use of time compositing procedures. For example, if a digester is being sampled during a withdrawal that takes about 15 minutes, a sample can be taken during the first, second, and third 5-minute period. The three separate

samples should be brought back to the laboratory and composited into a single sample. If the sample is being analyzed for bacteria, viruses, or vector attraction reduction, the composite should be prepared within an hour of collecting the first individual grab sample. A longer time period might allow microbiological changes to occur in the first sample taken. Composite sampling over 24 hours is possible for viable helminth ova analysis, provided that the ova in the sample are not exposed to chemical or thermal stress such as temperatures above 40°C (104°F) or certain chemicals such as ammonia, hydroxides, and oxidants.

Sampling Sewage Sludge in Tanks

The purpose of the sampling is to determine the properties of the entire mass of the sewage sludge, rather than, for example, to find out if there is a gradient in the property at various points in the tank. This requires that the tank be well-mixed, otherwise many subsamples must be taken throughout the tank and composited. Large tanks, even if they are well-mixed, have the potential for developing gradients in composition. An enclosed tank such as an anaerobic digester must be sampled through pipelines entering the digester. A minimum of three taps on a side wall of the enclosed tank is recommended. The sample tap pipe should project several feet into the tank. Precautions must be taken to minimize contamination from sample collection lines. When a sample is taken, enough material must be withdrawn to thoroughly flush the line before the sample is collected. This helps flush any contaminants in the sample line and assure that a representative sample is collected from the tank. The sample line should be backflushed with water after the sample is withdrawn to clean out residual sewage sludge and prevent microbial growth. Sampling should be conducted when the tank is being agitated. An open tank such as an aerobic digester can be sampled by drawing a vacuum on a vacuum-filtering flask connected to a rigid tube lowered to the desired level in the tank. A weighted sampling bottle may also be used to sample the liquid at the desired depth in the tank (see ASTM E30086, Par. 21, in ASTM [1992a]).

9.7 Sampling Thick Sewage Sludges

If sewage sludges are above 7% solids, they take on "plastic" flow properties; that is, they require a finite shear stress to cause flow. This effect increases as the solids content increases. Solids may thicken in lagoons to 15% solids. At these concentrations, they will not flow easily and require a substantial hydrostatic head before they will flow into a sample bottle.

Sampling of sewage sludge stored in lagoons may be very difficult, depending on the objectives of sampling and the nature of the sewage sludge in the lagoon. The thickened sewage sludge solids are generally nonuniformly distributed in all three dimensions. It is desirable first to map the distribution of depth with length and width to determine where the sampling should be concentrated. A length-width grid should be established that takes the nonuniformity of the solids deposit into account. ASTM E300-86, Figure 19 (ASTM, 1992a), shows a grid for sampling a uniform deposit in a railroad car.

The layer of water over the sewage sludge complicates the use of many types of tube samplers because the overlying water should not be included in the sample. A thief sampler (ASTM, 1992a) that samples only the sewage sludge layer may be useful. Weighted bottle samplers (ASTM, 1992a) that can be opened at a given depth can be used to collect samples at a desired depth. Samples at three depths can be taken and composited. Most likely the sewage sludge will be as much as twice as high in solids content at the bottom of the sewage sludge layer as at the top. Compositing of equal volumes of samples from top, middle, and bottom produces an excellent mass-average sample and adjusts for this difference in solids content. Generally there is no point in determining the gradient with depth for microbiological and VAR parameters, because there is no practical way of separately removing layers of sewage sludge from a lagoon. Determining whether there are gradients with length and width makes more sense because, if desired, sewage sludge could be removed selectively from part of a lagoon, leaving behind the unacceptable material.

Sewage sludges from dewatering equipment such as belt filter presses and centrifuges can have a solids content up to 35% and even higher following some conditioning methods. High solids content sewage sludges are easy to sample if they are on moving conveyors, as described in Section 9.5. However, if the sewage sludge is stored in piles, obtaining a representative sample requires more planning and a greater overall effort. As a result of the different environment between the pile surface and interior a gradient will develop over time in the sewage sludge storage pile. The sampling methodology used needs to address this potential gradient between the pile surface and interior. Sampling devices such as augers (a deeply threaded screw) are used on high solids cakes (ASTM, 1992a) to collect a cross sectional sample. The auger is "turned into the pile and then pulled straight out. The sample is removed from the auger with a spatula or other suitable device." Alternatively, a shovel can be used to collect subsamples for compositing from the pile interior. The pile should be sampled in proportion to its mass; more samples are taken where the pile is deeper.

9.8 Sampling Dry Sewage Sludges

For purposes of this discussion, "dry" sewage sludges contain as much as 60% water. They include heat dried and composted sewage sludges, and sewage sludges from dewatering processes, such as pressure filtration, that produce a cake which is usually handled by breaking it up into pieces. Some centrifuge cakes are dry enough that they are comprised of small pieces that remain discrete when piled.

Dry sewage sludges are best sampled when they are being transferred, usually on conveyors. Preferably material across the entire width of the conveyor is collected for

a short period of time. Several of these across-width samples are collected and combined into a time-composite sample. If the entire width of the conveyor cannot be sampled, the sample is collected from various points across the breadth of the conveyor, and a space and time-composited sample is collected.

Collecting a representative sample from a stockpile containing a dried sewage sludge product poses a greater challenge than collecting the sample from a conveyor. The settling and classification of the material and the different environments between the pile edge and interior must be considered. When a material comprised of discrete particles is formed into a pile, classification occurs. If the particles are homogeneous in size and composition, a representative sample can be easily obtained (assuming the sample is collected within 24 hours of pile construction). However if the particles are of a different size or composition, an unequal distribution of the particles may result during settling. For example, a composted sewage sludge may be heterogeneous, with respect to particle composition, even when oversized bulking agents have been removed. It is important that the edges and interior of such piles are properly weighted as part of the sample collection procedure. A sampling grid that prevents bias, such as that presented in ASTM E300-86, Item 31.4 (ASTM, 1992a), should be used.

The heterogeneous nature and presence of large particles in some composted sewage sludges cause another problem in sampling. For example, most augers and sampling thiefs will be ineffective in getting a representative sample from the interior of a pile containing large wood chips and fine composted sewage sludge. There may be no substitute for digging with a shovel to get to the desired location.

Stockpile sampling is also made more difficult by the constant evolution of the characteristics of stored material. Immediately after a sewage sludge stockpile is constructed, physical, chemical, and biological changes begin to occur within and on the surface of the stockpile. Within a period as short as 24 hours, the characteristics of the surface and outer part of the pile can differ substantially from that of the pile interior. The outer part of a pile tends to remain at or near ambient temperature, loses moisture through evaporation, and volatilizes some compounds such as ammonia. In contrast, pile interiors retain heat (achieving temperatures that can be 40°C greater than the pile surface), but lose little moisture or chemical compounds through evaporation and volatilization. As a result, the level of microbial growth and activity within the pile and on the pile surface will also differ. The potential for growth of fecal coliform bacteria in mesophilic regions of the pile is of particular concern. If a sewage sludge stockpile is more than one day old, the sample should be collected from a pile cross section. This is especially important when there is a large temperature gradient between the pile surface and interior.

9.9 Control of Temperature, pH, and Oxygenation After Sample Collection Samples for Microbial Tests

Table 9-2 summarizes the maximum holding times and temperatures for sewage sludge samples taken for microbial analyses. All samples should be cooled to appropriate temperatures immediately after they are collected to minimize changes in indicator organism and pathogen populations. For example, enteric viral and bacterial densities are noticeably reduced by even 1 hour of exposure to temperatures of 35°C (95°F) or greater. The requirement for cooling limits the practical size of the sample collection container. A gallon sample bottle takes much longer to cool than a quart bottle. Use of bottles no larger than a quart is recommended for most samples, particularly if the sewage sludge being sampled is from a process operated at above ambient temperature. Granular solids and thick sewage sludges take a long time to cool, so use of containers smaller than one quart is advised. For rapid cooling, place the sample container in a slurry of water and ice. Placing the sample container in a cooler containing bagged ice or "blue ice" is effective in maintaining low temperatures but several hours can elapse before this kind of cooling reduces sample temperature to below 10°C (50°F) (Kent and Payne, 1988). The same is true if warm samples are placed in a refrigerator. The presence or absence of oxygen is not a serious concern for the microbiological tests if the samples are promptly cooled.

Table 9-2. Analytical Methods Required Under Part 503

Analysis	Methodology	Maximum Holding Time[3]/Temperature
Enteric Viruses	American Society for Testing and Materials Method D 4994-89 (ASTM, 1992b)[1]	-18°C (0°F); up to 2 weeks
Fecal Coliform	Standard Methods Part 9221 E or Part 9222 D (APHA, 1992)[2]	4°C (39.2°F) (do not freeze); 24 hours
Salmonella sp. Bacteria	Standard Methods Part 9260D (APHA,1992)[2] or Kenner and Clark (1974) (see Appendix G of this document)	4°C (39.2°F) (do not freeze); 24 hours
Viable Helminth Ova	Yanko (1987) (see Appendix I of this document)	4°C (39.2°F) (do not freeze); 1 month
Specific Oxygen Uptake Rate (SOUR)	Standard Methods Part 27108 (APHA,1992)	20°C (sewage sludge must be digested in the 10-30°C range); 2 hours
Total, Fixed, and Volatile Solids	Standard Methods Part 2540G (APHA.,1992)	NA
Percent Volatile Solids Reduction	Appendlix C of this document	NA

[1] Appendix H of this document presents a detailed discussion of this method.

[2] Method SM-9221 E, the MPN procedure, is required for analysis of Class A biosolids and recommended for Class B biosolids. Method SM-9221 D, the membrane filtration procedure is also allowable for Class B biosolids. See Appendix F of this document for recommended sample preparation procedures and a discussion of the reporting of results.

[3] Time between sampling and actual analysis, including shipping time.

Standard Methods (APHA, 1992) states that if analysis for bacterial species (fecal coliform and *Salmonella* sp.) will commence within 1 hour after sample collection, no temperature adjustment is required. If analysis will commence between 1 and 6 hours after collection,the sample should be immediately cooled to at least 10°C. If analysis will commence between 6 and 24 hours after collection the sample should be immediately cooled to 4°C. The sample should never be frozen and analysis must commence within 24 hours of collection.

Proper planning and coordination with the courier service and analytical laboratory are essential if bacterial analyses are to be conducted within 24 hours of sample collection. The laboratory needs to be notified several days in advance so they can be prepared to initiate the analysis within several hours of receiving the sample. If they are not notified, the laboratory may not be adequately prepared and another day may lapse before the samples are analyzed. Actual sample collection should be conducted in the afternoon, within a few hours of the sample courier's arrival. If the samples are collected in the morning, a greater than 24-hour period may pass before the laboratory actually begins the analysis.

Follow-up with the laboratory is important to determine the actual sample holding time and temperature of the sample when it was received. This information can be used to improve the overall sample collection and transfer procedure. Feedback received from the lab regarding sample condition and holding times may also provide an explanation for erroneous or unexpected test results.

The requirement for prompt chilling of samples is appropriate for viruses as well as bacteria. There are far fewer laboratories capable of carrying out virus tests than can conduct bacterial analyses, so time between sample collection and analysis can routinely exceed 24 hours. Fortunately, viruses are not harmed by freezing. Typically, virology laboratories store samples at -70°C (-94°F) before analysis. Samples can be frozen in a -18°C (0°F) freezer and stored for up to 2 weeks without harm. Samples should be frozen, packed in dry ice, and shipped overnight to the analytical laboratory.

Viable helminth ova are only slightly affected by temperatures below 35°C (95°F), provided chemicals such as lime, chlorine, or ammonia are not utilized in the treatment process. Nevertheless, chilling to 4°C (39.2°F) is advised. If the samples are held at this temperature, a period of a month can elapse between sampling and analysis. Freezing should be avoided because the effect of freezing on helminth ova is not well understood.

Vector Attraction Reduction Tests

For the vector attraction reduction tests that measure oxygen uptake, or additional anaerobic or aerobic digestion (see Appendix D), the samples must be kept at the temperature at which they were collected. This sometimes can be done just by collecting a large sample in a large container. Covering the sample with an insulating blanket or placing it in an insulated box provides adequate protection against temperature change in most cases. Desired temperature can be maintained in the box by adding a "hot water bottle" or a bag of blue ice.

Depending on whether the sewage sludge is from an aerobic process or anaerobic digestion, the presence or lack of oxygen will determine which vector attraction reduction test is appropriate and therefore how the sample should be handled. For aerobic sewage sludges, a lack of oxygen will interfere with the metabolic rate of the aerobic microorganisms in the sample. Similarly, presence of oxygen will seriously affect or even kill the anaerobic organisms that convert organic matter to gases in anaerobic digestion. With samples taken for SOUR analysis, it has been the experience of some investigators that if the test is not run almost immediately after collection (within about 15 minutes), that erroneous results are obtained. The additional aerobic digestion test is more "forgiving" (because it is a long-term test and shocked bacteria can revive); up to 4 hours of shortage of oxygen can be tolerated. For the additional anaerobic digestion test, the sample containers should be filled to exclude air. In any subsequent operations where there is a freeboard in the sample or testing vessel, that space should be filled with an inert gas such as nitrogen.

No pH adjustment is to be made for any of the vector attraction reduction tests. For those vector attraction processes that utilize lime, the only requirement is to measure pH after the time periods indicated in the vector attraction reduction option (see Section 8.7).

9.10 Sample Compositing and Size Reduction

The amount of sample collected in the field generally far exceeds the amount needed for analysis. The field sample must therefore be reduced to a manageable size for the analyst to handle. As for all sample handling, sample size reduction is more difficult for microbial samples than for samples taken for vector attraction reduction tests because of the potential for microbial contamination. The laboratory may be better equipped to perform subsampling than samplers in the field.

Microbial Tests

Freely flowing liquid samples can be adequately mixed in the sample bottles by shaking the bottles. There must be room in the bottle for adequate mixing. Compositing of smaller samples is accomplished by pouring them into a larger bottle with adequate freeboard and mixing it by shaking or stirring it thoroughly with a sterile paddle. Pouring off a portion of the contents of a large container into a smaller bottle is not an acceptable procedure because the top layer of any slurry always contains fewer solids than do lower layers. Sampling with a pipette with a wide bore is an acceptable alternative, provided the bore of the pipette does not restrict the entry of solid particles. The

sample should be drawn into the pipette slowly and the tip moved through the sample to minimize selective collection of liquid over solid particles.

Sample size reduction for thick sewage sludges is difficult, because they cannot be mixed by shaking. Stirring with a mechanical mixer or a paddle is often inadequate (recall how long it takes to mix a can of paint). A satisfactory approach is to hand mix a composite of subsamples, and then take a large number of small grabs from the composited sample to form the smaller sample for the analyst.

Dry solids samples can generally be mixed adequately by shaking if there is sufficient head space in the sample container, but the individual particles are frequently large and must be reduced in size to get a representative sample. If the particles are large and a number of subsamples must be combined into a large composite, it may be necessary to reduce the particle size before they are composited. This can be done in a sterile covered chopper, blender, or grinder. The individual subsamples are then combined and mixed by shaking, rotating, and tumbling. A smaller composite is then prepared by combining a number of grabs from all parts of the combined sample. Many facilities do not have adequate equipment needed to perform this size reduction procedure. However, most analytical laboratories have this capability and will typically perform this procedure at a nominal cost. Coordination with the analytical laboratory regarding subsampling is an important part of the sampling and analysis procedure that should not be ignored. Some other sample size reduction methods, such as "coning and quartering" (ASTM, 1992a) may be use only if aseptic handling practices are observed. It should be noted that particle size reduction is not appropriate if the large pieces in the sample are not sewage sludge but are other materials which have been added to the sewage sludge for processing purposes. For the purpose of microbial or volatile solids reduction testing, additives such as wood chips should be removed from the sample before size reduction or sample preparation (see Section 10.5). It is recommended in these cases that a one-quarter inch mesh sieve be used for this purpose.

Vector Attraction Reduction Tests

The lack of a need to prevent microbial contamination makes compositing and size reduction easier for vector attraction reduction tests than for the microbial tests. However, there is a need to keep the aerobic samples aerobic and to prevent the anaerobic samples from coming into contact with air. Subsamples for the anaerobic tests can be collected into individual bottles at the sampling location. As noted above, these sample bottles should be filled completely and capped. A brief exposure to air will not cause a problem, but any prolonged exposure, such as might occur when several subsamples are being blended together and reduced in size for a representative composite sample, must be avoided. One acceptable sample size reduction procedure is to flush a large sterile bottle with nitrogen, then pour in the subsamples and blend them together with nitrogen still bleeding into the vessel. Alternatively, the nitrogen-filled vessel could be flushed with more nitrogen after the admission of the subsamples, capped, and then shaken thoroughly to accomplish the blending. Analytical laboratories generally can perform this size reduction procedure.

9.11 Packaging and Shipment

Proper packaging and shipment are important to ensure that the samples arrive in good condition (proper temperature, no spillage) within the specified time frame.

Sealing and Labeling Sample Containers

Sample containers should be securely taped to avoid contamination, and sealed (e.g., with gummed paper) so it is impossible to open the container without breaking the seal. Sealing ensures that sample integrity is preserved until the sample is opened in the laboratory. A permanent label should be affixed to each sample container. At a minimum the following information should be provided on each sample container:

- Type of analysis to be performed (e.g., *Salmonella* sp., fecal coliform bacteria, enteric virus, or viable helminth ova)
- Sample identification code (if used) or a brief description of the sample (that distinguishes it from other samples) if no sample code system is used
- Sample number (if more than one sample was collected at the same point on the same day)

Other information may include:

- Facility name, address and telephone number
- Date and time the sample was taken
- Facility contact person

This information should also be included on an enclosed chain of custody form.

Shipment Container

A soundly constructed and insulated shipment box is essential to provide the proper environment for the preserving sample at the required temperature and to ensure the sample arrives intact. Small plastic cased coolers are ideal for sample shipping. It is recommended that the outside of the shipment container be labeled with the following information:

- The complete address of the receiving laboratory (including the name of the person responsible for receiving the samples and the telephone number)
- Appropriate shipping label that conforms to the courier's standards
- Number of samples included (i.e. "This cooler contains 10 samples")

- The words “Fragile” and “This End Up”

To maintain a low temperature in the shipment box, a blue-ice type of coolant in a sealed bag should be included in the box. If the blue ice has been stored in a 0°F (-18°C) freezer (e.g., a typical household freezer), the coolant should be “tempered” to warm it up to the melting point of ice (0°C [32°F]) before it is placed around the sample. Additional packing material (bubble wrap, Styrofoam peanuts, balled-up newspaper) should be placed in the shipping container to fill in empty space to prevent sample containers from moving and potentially breaking or spilling during shipping. It is also recommended that the courier be contacted in order to determine if there are any special requirements for the shipping of this type of sample.

Adherence to Holding and Shipment Times

Adherence to sample preservation and holding time limits described in Section 9.6 is critical. Samples that are not processed within the specified time and under the proper conditions can yield erroneous results, especially with the less stable microorganisms (i.e., bacteria). Make sure the analytical laboratory reports the date and time when the samples arrived, and total holding time (period from when the sample was collected to the initiation of analysis). This information will be valuable for improving future sample events and maintaining quality control.

9.12 Documentation

Sampling Plan

It is recommended that all procedures used in sample collection, preparation, and shipment be described in a sampling plan. At a minimum, a sampling plan should provide the following information:

- Sample collection locations
- Volume of sample to be collected
- Sample compositing procedures
- Days and times of collection
- Required equipment
- Instructions for labeling samples and ensuring chain of custody
- A list of contact persons and telephone numbers in case unexpected difficulties arise during sampling

If a formal sampling plan is not available, a field log that includes instructions and a sample collection form may be used (EPA, 1980).

Sampling Log

All information pertinent to a sampling event should be recorded in a bound log book, preferably with consecutively numbered pages. At a minimum, the following information should be recorded in the log book.

- Purpose of sampling event
- Date and time of sample collection
- Location where samples were collected
- Grab or composite sample (for composite samples, the location, number, and volume of subsamples should be included)
- Name of the person collecting the sample(s)
- Type of sewage sludge
- Number and volume of the sample taken
- Description of sampling point
- Date and time samples were shipped

Chain of Custody

To establish the documentation necessary to trace sample possession from the time of collection, it is recommended that a chain-of-custody record be filled out and accompany every sample. This record is particularly important if the sample is to be introduced as evidence in litigation. Suggested information for the chain-of-custody record includes, at a minimum:

- Collector’s name
- Signature of collector
- Date and time of collection
- Place and address of collection
- Requested preprocessing (subsampling, compositing, particle size reduction)
- Requested analyses
- Sample code number for each sample (if used)
- Signatures of the persons involved in the chain of possession

A good rule of thumb is to record sufficient information so that the sampling situation can be reconstructed without reliance on the collector’s memory. Chain-of-custody forms can be obtained from the laboratory and should be used even if the laboratory is on-site and part of the treatment facility.

9.13 Analytical Methods

Part 503.8(b) of the Part 503 regulation specifies methods that must be used when analyzing for enteric viruses; fecal coliform; *Salmonella* sp.; viable helminth ova; specific oxygen uptake rate; and total, fixed, and volatile solids. Table 9-2 lists the required methods. Complete references for these methods can be found in Chapter 12, and recommended sample preparation and analytical methods can be found in the appendix as listed below.

Calculating volatile solids reduction	Appendix C
Conducting additional digestion and specific oxygen uptake rate (SOUR) tests	Appendix D
Determination of residence time in digesters	Appendix E
Sample preparation — fecal coliform and *Salmonella* sp. analysis	Appendix F
Analytical method — *Salmonella* sp.	Appendix G
Analytical method — enteroviruses in sewage sludge	Appendix H
Analytical method — viable helminth ova	Appendix I

As of the time of publication of this document, the allowable analytical methodologies are as listed above. However, in the case of fecal coliform analysis for Class B-Alternative 1, it is recommended that the MPN method be used instead of the membrane filter test (the MPN method is required for Class A fecal coliform analysis), and that the Kenner and Clark methodology be used for *Salmonella* sp. analysis.

9.14 Quality Assurance

Quality assurance involves establishing a sampling plan and implementing quality control measures and procedures for ensuring that the results of analytical and test measurements are correct. A complete presentation of this subject is beyond the scope of this manual. A concise treatment of quality assurance is found in Standard Methods (APHA, 1992) and is strongly recommended. Parts 1000 to 1090 of Standard Methods are relevant to the entire sampling and analysis effort. Part 1020 discusses quality assurance, quality control, and quality assessment. Standard Methods (Part 1020B) states that "a good quality control program consists of at least seven elements: certification of operator competence, recovery of known additions, analysis of externally supplied standards, analysis of reagent blanks, calibration with standards, analysis of duplicates, and maintenance of control charts." For most of the tests to be carried out to meet the pathogen and vector attraction reduction requirements of the Part 503 regulation, these elements cannot be met completely, but they should be kept in mind as a goal.

Microbial Tests

For the microbiological tests, quality assurance is needed to verify precision and accuracy. Quality assurance for microbiological methods is discussed in Part 9020 of Standard Methods. The quality control approach suggested is recommended for the microbiological tests required by the Part 503 regulation. In Part 9020B-4, Analytical Quality Control Procedures, it is suggested that precision be initially established by running a number of duplicates, and that thereafter duplicates (5% of total samples) be run to determine whether precision is being maintained.

Spiking and recovery tests are an important part of quality assurance. Yanko (1987) has found that spiking is useful for the viable helminth ova test, but that testing recovery effectiveness on unspiked sewage sludge is more useful for quality assurance for bacterial or viral tests. With either method, the density of the measured pathogens should be at levels that are relevant to the Part 503 regulation. For example, for viable helminth ova, samples should be spiked to density levels of approximately 100 per gram. Recovery of bacteria and viruses should be conducted on primary sewage sludges that typically contain viruses at low but consistent levels (such as primary sewage sludges from large cities).

For both commercial and in-house laboratories, quality assurance procedures should be incorporated into the analytical method and assessed routinely. Communication with the analytical personnel is an important part of developing a good sampling and analysis protocol. The sewage sludge preparer should review quality assurance data along with analysis results to ensure that laboratory performance is acceptable.

Vector Attraction Reduction Tests

It is not possible to test for accuracy for any of the vector attraction reduction tests, because standard sewage sludges with consistent qualities do not exist. Standard Methods gives guidance on precision and bias. However, for some of the vector attraction reduction options, this information was not available or was approximate. Section 10.7 provides guidance on the number of samples to take. The procedures for three of the vector attraction options developed for the Part 503 regulation (additional anaerobic and aerobic digestion and the specific oxygen uptake rate test), which are presented in Appendix D, have internal quality control procedures that include replication. Since the tests are newly proposed, the data are insufficient to judge whether agreement between replicates is adequate. This kind of information will be communicated as experience with these options accumulates.

Chapter 10
Meeting the Quantitative Requirements of the Regulation

10.1 Introduction

The Part 503 regulation contains operational standards for pathogen and vector attraction reduction. It provides only minimal guidance on the amount of information that must be obtained during a monitoring event to prove that a standard has been met or to demonstrate that process conditions have been maintained. This document provides more detailed information for regulators and facilities on how to adequately satisfy the regulatory requirements. Some frequently asked questions and answers are also included at the end of this chapter.

In general, it has been found that the daily, weekly, and seasonal fluctuations that occur in wastewater treatment works and sludge quality make it difficult to adequately represent sludge quality with minimum sampling. It is therefore recommended that multiple samples be taken for any sampling event and that samples be taken over a minimum 2-week period in order to best represent the performance of a sludge treatment process. Although extensive-sampling is time consuming and facility operators are often under pressure to reduce costs, it is strongly recommended that multiple samples be included in a sampling plan so that the variable quality of sludge can fully be understood.

There are many types of wastewater treatment plants and sludge management practices. This document addresses some of the many operational variables and provides some examples of how to demonstrate compliance with the regulations. The final decision about what to monitor and how frequently to monitor it lies with the permitting authority who may impose permit conditions based on specific parameters including the type of sludge produced, its intended usage, and/or the history of the facility.

10.2 Process Conditions

Sufficient information must be collected about sludge processing conditions and made available to the permitting authority and any other interested parties to enable a qualified reviewer to determine if the Part 503 requirements have been met. How this information is collected and how much information is needed depend on the process. The following example illustrates the type of information and the level of detail that may be included in a permit application. Consider the case of a treatment works that meets the pathogen reduction requirement for a Class B sludge by using anaerobic digestion conducted at the PSRP conditions of 35°C (95°F) with a 15-day residence time. To meet the pathogen reduction requirement, the monitoring results must demonstrate that the 35°C (95°F) temperature and 15-day residence time are maintained whenever the process is being used. The example below illustrates some of the factors to be considered in assuring compliance with the regulation. In addition, a contingency plan in case the conditions are not met, and product usage should be specified.

Example

Facility	Clarksdale Wastewater Treatment Facility Anaerobic Digestion
Size:	300 dry metric tons per year
Class:	B

Sewage sludge is treated in two digesters, operated in parallel, fed by constant displacement progressive cavity pumps. The facility complies with PSRP requirements by maintaining sludge at a temperature at or above 35°C for a minimum of 15 consecutive days.

- Temperature — During the first six months of operation under this permit, the permittee shall perform temperature scans throughout the volume of the digester to establish the location of the zone at which temperature is at a minimum. Scans will be conducted under the expected range of operating conditions. Once the location of the zone is established, the permittee will continuously measure digester temperature in the zone of minimum temperature. Temperatures will be recorded continuously or at intervals of eight hours. The temperature measuring device will be calibrated on a monthly basis.

- Retention Time — The permittee shall calculate the working volume of the digester to determine residence time. The permittee shall provide evidence that the digester has been cleaned within the last two years, or alternatively, determine the levels of grit and scum accumulation. Residence time must be at least 15 days. Flow rate and residence time will be measured and calculated each year.

- Vector Attraction Reduction - The facility will comply with vector attraction reduction via management practices. After digestion, the sludge will be dewatered and transported to farm land where it will be land applied and disked immediately (within six hours) into the soil (see below). Sludge will not be stored at application sites.

- Reporting- The data collected throughout the year will be summarized and submitted to the permitting authority annually. Reports will include temperature and residence time records as well as records of all application sites and sludge application rates.

- Contingency Plan -If the facility fails to meet the 35° C/15-day requirement, it has several options. The facility can try to meet the Class B time/temperature requirement with lower temperatures and longer residence times as determined by a linear interpolation between 35ºC (95°F) and 15 days and 20ºC (68°F) and 60 days. If the facility does not have the flexibility to maintain sludge in the digester for longer than 15 days, it can meet Class B requirements by sampling the sludge for fecal coliform and demonstrating that the sludge contains less than 2 million CFU or MPN per gram of sludge on a dry weight basis. Alternatively, the facility can dispose of the sludge by means other than land application. In the case that the facility cannot meet the time/temperature requirements, the permitting authority must be contacted so that a sampling plan which adequately represents sludge quality and demonstrates Class B pathogen reduction can be designed. If the facility decides to divert the sludge from land application, it must notify the regulatory agency of its plans.

- Product Use - The sludge will be land applied in accordance with all Part 503 restrictions. The facility will distribute the Class B sludge to local fruit farmers. The facility will notify applicators of sludge quality and relevant site restrictions. Crop harvesting will be restricted in accordance with Part 503 site restrictions. In the case of application to fruit trees, the farmer will wait a minimum of 30 days after application to harvest the fruit. If fruit that has fallen off the trees or otherwise touched the ground will also be harvested, the farmer will wait 14 months after sludge application to harvest the fruit. If there is any question about the waiting period or if the facility wishes to distribute sludge to farmers of crops which touch the ground, the facility should notify the regulator. Site restrictions for crops which touch the soil or which grow below the soil surface are subject to longer waiting periods.

The number and the level of detail of a permit's conditions vary depending on the type of process. Facilities that handle sludge or septage from more than one source should be subject to more frequent testing until they can demonstrate that the product consistently meets quality standards. The permitting authority must determine at what point the facility has adequately demonstrated consistency and can reduce the level of sampling.

For example, consider a treatment facility that collects liquid sewage sludge and septage from several different sources. Although all of the sludge collected undergoes standard treatment for Class B pathogen reduction, the quality of the sludge generated may vary depending on the particular feedstock received. Initially, the permitting authority may require this facility to monitor every batch of sludge in order to demonstrate that it consistently produces sludge in compliance with regulatory and permit requirements. Eventually, if enough data is available showing that the treated sewage sludge is rarely off specification, the sampling frequency could be reduced.

For other processes, such as static pile composting, a sampling plan might specify that one of several piles constructed in a day could be monitored, probably with several thermocouples at different elevations and locations in the pile, to demonstrate conformance for the whole day's production.

At times, processes do not conform to process conditions. In such cases, the operator should keep records showing that the treated sludge produced was either recycled to be processed again or diverted in some manner for use or disposal consistent with its quality (e.g., disposal in a landfill with daily cover or, if the sludge meets the Class B requirements, application as a Class B [rather than as a Class A] biosolids).

10.3 Schedule and Duration of Monitoring Events

For purposes of this discussion:

- A sampling event is defined as the period during which samples are collected. Samples may include several independently analyzed subsamples taken during the sampling event.

- A monitoring event includes the sampling period and the period to analyze the samples and provide the results needed to determine compliance.

Monitoring events are intended to reflect the typical usual performance of the treatment works. Conditions should be as stable as possible before the monitoring event. Day-to-day variations in feed rate and quality are inevitable in sewage sludge treatment, and the processes are designed to perform satisfactorily despite these variations. However, major process changes should be avoided before monitoring events, because long periods of time --as much as 3 months if anaerobic digestion is part of the process train-- are required before steady state operation is reestablished.

Monitoring for Microbiological Quality

To meet the Part 503 pathogen reduction requirements, sewage sludges may have to be monitored to determine densities of fecal coliforms, *Salmonella* sp., enteric viruses,

and/or viable helminth ova. Monitoring for these microorganisms presents special problems, primarily caused by the length of time it takes to obtain microbiological test results. This is a function of the time it takes to deliver the samples to a laboratory, have the tests conducted, and obtain the results. Microbiological analyses require a substantially longer period than conventional physical and chemical analyses. The approximate time to complete specific microbiological analyses is summarized as follows.

Fecal coliform (MPN), 4 days
Salmonella sp. (MPN) 5 to 7 days
Enteric viruses, 14 days
Viable helminth ova, 28 days

Variations in the microbiological quality of the treated sludge and intrinsic variation in the analytical methods are generally large enough that a single measurement of a microbiological parameter is inadequate to determine whether a process meets or fails to meet a requirement. The Pathogen Equivalency Committee recommends that the monitoring event include at least seven samples taken over a period of approximately 2 weeks (see Section 10.7). Based on the reliability of the treatment process and historic test results, there may be times when a reduction in this monitoring recommendation is justified.

Thus, the time required for a monitoring event could range from 3 to 7 weeks. During this time, the quality of the treated sewage sludge generated is unknown. As discussed in Section 4.10, classification of sludge as Class A or B is based on the most recent test results available. Therefore, material can continue to be distributed under its classification as Class A or B until more recent analytical results are available. However, it is recommended that material generated during the monitoring event be retained on site until results from the monitoring event are available. This will prevent misclassified sludge from being erroneously distributed.

For example, consider a facility producing a Class A sludge that is sampled for *Salmonella* sp. analysis every quarter. All historic data has shown the facility to be in compliance with Class A standards including the most recent set of lab analyses from the January monitoring event. Under these results, materials are distributed as Class A products even throughout April when a subsequent monitoring event takes place. This is acceptable because material is still classified under the most recent available lab result. However, suppose the April results show non-compliance with Class A standards. Despite the fact that the preparer complied with regulations, it is possible that some Class B material was inadvertently distributed for Class A use.

In order to avoid this situation, it is recommended that the sludge processed during the monitoring event either be stored until it is demonstrated that the processed sludge meets the quality requirements for use as a Class A or B sludge, or - if the sludge is being monitored for Class A requirements - used or disposed as a Class B sludge (provided it meets the Class B requirements). This may take up to 3 weeks in the case of fecal coliform or *Salmonella* sp. analysis and much longer if sludge is being analyzed for helminth ova or viruses. Contingencies for this type of situation should be discussed with the regulatory authority and included in permit conditions and operational plans. (For more discussion on the timing of sampling and distribution, see Section 4.10.)

Monitoring for Vector Attraction Reduction

Not all the vector attraction reduction options listed in the regulation (see Chapter 8) require lab testing. Four of the methods (treatment of sewage sludge in an aerobic process for 14 days or longer, injection below the surface of the land, incorporation of sludge into the land, and placement of sludge on a surface disposal site and covering it at the end of each day) are technology descriptions. These technologies have to be maintained throughout the year in the manner described in the regulation. Examples of the kind of information needed to demonstrate adequate performance are provided in Section 10.2.

The remaining vector attraction reduction options are based on laboratory testing for volatile solids reduction, moisture content, or oxygen uptake reduction. Some of the options can only be used with certain sludge processes. For example, the oxygen uptake rate test is only appropriate for a sludge from any aerobic digestion or wastewater treatment process. Other options, such as the 38 percent reduction in volatile solids, can be applied to a variety of biological sludge treatment processes. In any case, the technology aspect of the option, or the process by which vector attraction reduction is being attained, must be documented in the manner described in Section 10.2. Monitoring for vector attraction reduction should be performed at a minimum according to the required monitoring schedule.

Some tests for vector attraction reduction can be conducted within a few hours while others can take more than a month. For the tests that can be conducted within a few hours, the sampling event must be more than a few hours to account for the variability in the material tested and the performance of the vector attraction reduction process as affected by the changes in feedstock.

It is suggested in Section 8.14 that facilities maintain a sampling program that involves sampling at evenly spaced time intervals throughout an established monitoring period. The on-going samples can be used to calculate running averages of volatile solids reduction which are more representative than single samples or an attempt to correlate feed sludge and sludge product. As is the case for the microbiological tests, these vector attraction reduction tests should be conducted over approximately 2 weeks to minimize the expected effect of these variations. The 2-week period can be the same 2-week period during which the microbiological parameters are being determined.

The longer VAR tests present a similar problem as monitoring for microbiological quality. Some of the tests - such as the additional digestion tests - take more than a month to complete. Unless the treatment works has several sets of duplicate testing equipment, it will be impossible to run these tests on enough samples during a 2-week sampling period to assess the variability in the performance of the treatment process. Storing samples taken during this period until the equipment becomes available is not an option, because samples cannot be stored for more than a limited time period (see Section 9.6.) In such circumstances, the preparer may wish to run the vector attraction reduction tests more frequently than required in order to demonstrate on-going compliance with the requirements. More frequent testing will indicate if the facility is performing consistently and will reduce the need for multiple samples during the sampling period.

The preparer may wish to conduct composite sampling which combines samples taken within a 24-hour period to better represent sludge quality. (See Section 10.6). Since some of the bench scale tests may be affected by long-term storage of samples, compositing should be limited to a 24-hour period. If composting is done, the composite should be held at 5°C during compositing, and the assay must begin immediately upon completion of the composite.

Preparers should discuss specific facility parameters with the permitting authority to design a sampling program that is appropriate.

10.4 Comparison of Feed Sludge and Sludge Product Samples

The enteric virus and viable helminth ova analytical requirements to demonstrate that an existing or new sludge treatment process is equivalent to a PFRP one and some of the vector attraction reduction methods (e.g., percent volatile solids reduction) involve taking input and output samples that correspond (i.e., they are “before processing” and “after processing” samples of the same batch of sludge). The comparison of input and output samples allows for the determination of whether enteric viruses and helminth ova levels are being reduced to adequate levels and/or percent volatile solids reduction.

Obtaining samples that correspond can be difficult for sewage sludge treatment processes, such as anaerobic digestion, that characteristically treat sludge in fully mixed reactors with long residence times. For example, as mentioned in Section 10.3, it can take up to 3 months for an anaerobic digester to achieve steady state operation after some substantive change in feed sludge or process condition is made. Samples taken only after the process has reached steady state operation are considered as corresponding.

Many of the treatment processes that might be considered for demonstrating equivalency to PFRP are either batch or plug flow processes. In theory it is relatively simple to obtain corresponding samples - it is only necessary to calculate the time for the input material to pass through the system and sample the downstream sludge at that time. Achieving accurate correspondence in practice, however, is seldom easy. Consider, for example, the difficulty of obtaining good correspondence of feed and treated sludge for a composting operation in which the feed sewage sludge is to be compared to composted sludge that has been stored for 3 months.

Taking multiple samples and appropriately compositing the samples of feed and treated sludge averages out the composition of these sewage sludges and reduces the correspondence problem. It is the regulatory authority’s task to determine how many samples should be taken and how much data is necessary to demonstrate reduction of microorganisms in corresponding samples. As indicated in Section 10.6, limitations on the periods of time over which microbiological samples can be collected limit the utility of compositing.

10.5 The Effect of Sludge Processing Additives on Monitoring

Many sewage sludge dewatering and stabilization processes introduce other substances into the sludge. With the exception of large bulky additives such as wood chips, there is no need to modify sampling and analytical procedures. As discussed below, additives such as wood chips can complicate sample preparation and analysis and are best removed prior to analysis.

Polymers, lime, ferric chloride, paper pulp, and recycled sludge ash are frequently used to aid in dewatering. Disinfection by alkaline treatment requires the addition of lime or other alkaline materials to increase the temperature of the sewage sludge cake to disinfecting temperature. These materials also reduce the microbial densities by dilution and increased solids content. However, the change in microbial density caused by dilution may not be substantial. For example, an increase in mass of 20% would result in a reduction in the log density of a microbiological parameter of only 0.079.

The exposure risk to human health is directly related to the mass of treated sludge. So the achievement of pathogen reduction requirements and safe end-use is dictated by the population of pathogenic organisms in the final product. This is the approach taken by the Part 503 regulation, which requires that the treated sludge, regardless of the mass of other materials added, meet the standards for Class A or Class B sludge.

For some sludges, particularly those treated by composting (these usually will be Class A biosolids), the amount of additive can be considerable. Nevertheless, the regulation requires that the biosolids meet the standard, which means that no correction need be made for dilution.

The issues of sampling and analytical procedures for employment are different when considering wood chips or other materials which are often added to sludge as a bulk-

ing agent for composting. Compost product may be given away or sold as a screened or unscreened product, and although regulations require that the treated sludge, as it is applied, meets 503 standards, in the case of wood chips and other large particle size bulking materials, it is appropriate to remove large pieces before analysis takes place.

Large additives are removed in order to improve the accuracy of the microbial measurements. The wood chips are so big (typically 4 cm x 4 cm x 1 cm) that a very large sample would have to be taken and blended to get a representative subsample. Sample reliability is reduced when the sample consists of a mix of sludge solids and fibrous wood-chip residue from blending. Another reason for removing the wood chips prior to microbial analysis is that the exposure of users to the compost is related to the fine particle content and not to large, physically distinct wood chips. For example, a user who handles the compost gets his or her hands covered with compost particles. Similarly, the user might breathe in a dust of compost particles. In both cases, it is the "fines" of the compost, not the wood chips that the user is exposed to.

In order to ensure that wood chips are not included in the lab's subsample, the facility should remove wood chips after sampling, being careful not to contaminate, with a sterilized sieve. The size of the sieve needed depends on the dimensions of the wood chips, but the same sieve size should be used for each sampling event. Alternatively, the laboratory should be asked to remove wood chips from samples before subsampling or analyses are conducted. Again, the sieve size should be established so that a standard size is used.

10.6 Collecting Representative Samples

Sludge quality varies depending on the inputs to the wastewater system. In addition, the process is subject to ambient conditions which vary daily as well as seasonally. The goal of a sampling program is to adequately represent the quality of sludge. Therefore, both the frequency of sampling and the number of samples taken in any one sampling event must be considered carefully. This section discusses the issue of variability and how sampling frequency and composite sampling can improve the quality of data collected. A sampling plan is recommended for all sampling events to assure representative samples.

Random Variability

Virtually all sewage sludge treatment processes will experience a certain amount of short-term random or cyclic variation in the feed sludge and in process performance. Evaluation of average performance over a 2-week time period is suggested as a reasonable approach to account for these variations. Cyclic variation can be minimized by sampling on randomly selected days and time-of-day in a given week. In the case of Class B fecal coliform analysis **ONLY** variability is minimized by taking the geometric mean of analytical results. In the case of Class A, all samples must meet the fecal coliform or *Salmonella* sp. numerical limit.

Seasonal Variability

For some sewage sludge treatment processes, performance is poorer during certain parts of the year due to seasonal variations in such factors as temperature, sunshine, and precipitation. For example, aerobic digestion and some composting operations can be adversely affected by low ambient temperature. In such cases, it is critical that process performance be evaluated during the time of year when poorest performance is expected. If a treatment works is evaluated four or more times a year at intervals of 2 or 3 months, there is no problem, because all seasons of the year will be covered. For small treatment works that are evaluated only once or twice a year, it is important to monitor in the time of year where performance is expected to be poorest, to avoid approving a process that is not performing adequately for much of the year. It may also be beneficial to initially conduct sampling more frequently than the required minimum, perhaps on a quarterly basis, in order to determine the range of sludge quality. Process criteria of PSRPs and PFRPs should be discussed by the facility with the regulatory authority, and specific requirements should be included in permit conditions.

Composite Sampling

Composite sampling, or the combination of several grab samples to better represent a large quantity of sludge, is frequently practiced in wastewater treatment. Composites may consist of grab samples taken over time (typically for continuous flow processes) or from random locations in a vessel or pile (typically for batch processes). Since the purpose of composite sampling is to provide representation of a large quantity of sludge, the number and distribution of grab samples, the locations from where they are taken, and the process of combining grab samples to create a composite sample are important to consider.

The following is an example of a sampling procedure for compositing a continuous flow process. A small stream of wastewater or sludge is drawn off at rate proportional to the flow of the main stream being sampled and collected as a single sample. Typically, times of collection are for one shift (8 hours) or one day (24 hours). In this case, the accumulated sample represents a volume-average sample over the period of time the sample is drawn. The sample is chilled during the period it is being collected to prevent chemical/microbiological change until it can be brought back to the laboratory for analysis.

Composite sampling from stockpiled solid material involves taking multiple grab samples from a range of locations in the stockpile. Samples should be taken from different interior sections of the pile which may represent material produced in different time periods. Grab samples should all be of the same size so that the composite is an equal representation of all of the grab samples. The grab samples should be mixed thoroughly and a subsample pulled from the mixture.

Composite sampling is useful for any type of sampling, but the protocol must be modified when microbial analy-

ses are intended. Samples must be taken over a shorter period of time so that microbial populations do not undergo significant changes during the sampling event. For example, a composite time-average sample can be obtained by combining a series of small samples taken once every 5 minutes for a period of an hour. A composite sample for bacterial and viral testing could be taken over an hour or less under most circumstances without compromising the results. Composite sampling over 24 hours, or even longer if special precautions are taken, is possible for viable helminth ova provided the ova in the sample are not exposed to thermal or chemical stress (e.g., temperatures above 40°C [104°F] or the addition of certain chemicals such as ammonia, hydroxides, and oxidants). In addition to limiting the sampling period, sterile equipment must be used when taking grab samples or compositing the samples for microbiological analysis in order to prevent introducing pathogenic bacteria.

Composite sampling may be possible for samples to be used in some of the procedures to determine whether vector attraction reduction is adequate. It may not be appropriate for those procedures that depend on bacterial respiration (i.e., aerobic or anaerobic digestion). This subject is discussed in Appendix D which presents procedures for three methods to demonstrate reduced vector attraction.

10.7 Regulatory Objectives and Number of Samples that Should be Tested

Overall, it is recommended that numerous samples be taken over a period of 2 weeks in order to represent the average characteristics of a sludge stream. Unfortunately, sampling for microbial and vector attraction reduction parameters is more complicated than sampling for heavy metals because of the time limits and contamination issues involved. In addition, the results of microbial testing must be handled differently. The following is a review of the primary sampling and monitoring issues that relate to particular pathogen and vector attraction reduction parameters.

Class B: Monitoring for Fecal Coliform Densities

Part 503 requires that seven samples be taken to demonstrate compliance with the fecal coliform levels required of Class B biosolids. Under the Class B requirements seven samples also means seven analyses. Seven samples were judged adequate to account for the short-term fluctuations in treated sludge quality and allow determination of average performance. Variance of fecal coliform determinations is known to be high, but analysis (presented below) showed that if seven samples are averaged, the error band about the mean value is sufficiently compressed that treatment works with adequately treated sludge would not have difficulty meeting the standard. If the mean value does not meet the standard, the material is not a Class B biosolids and must be disposed of otherwise until the standard is met.

The regulation requires that the geometric mean fecal coliform density of the seven samples be less than 2 million CFU or MPN per gram of total solids sewage sludge (dry weight basis). If a treatment works were producing a treated sewage sludge with a true mean density of exactly 2 million fecal coliform per gram, measured values of the fecal coliform density would cluster around 2 million per gram, but half would be below and half would be above it. Half the time, the treatment works would appear not to be meeting the requirement. The true mean density must be below 2 million per gram to be confident that the experimentally determined average will be below 2 million per gram. Just how much below depends on the standard error of the average.

Use of at least seven samples is expected to reduce the standard error to a reasonable value. In tests on extended aeration sludges, Farrell et al. (1990) obtained a standard deviation of the logarithm of the fecal coliform density (s) of 0.3 using the membrane filter method. This included the variability in the analysis as well as variability over time (approximately a year). Standard error for the average of seven measurements (S.E.= $s/(n^{1/2})$)is 0.11. Using the normal probability distribution, the true mean must be below 1.30 million if the geometric mean of seven measurements is to be below 2 million 95% of the time (see Table 10-1 for details of this calculation). If the standard deviation were higher, the true mean would have to be even lower to be reasonably confident that the geometric mean would be below 2 million per gram. Thus, efforts should be made to reduce variability. Steps that can be taken are:

- Reduce the standard error by increasing the number of measurements used to determine the geometric mean.
- Reduce process variability.
- Improve sampling and analytical techniques.

What action to take to reduce the geometric mean depends on the process. For anaerobic or aerobic digestion, some suggested steps are to increase temperature, increase residence time, use a draw-and-fill feeding procedure rather than fill-and-draw or continuous feeding, and increase the time between withdrawal and feeding. After an attempt at improvement, the evaluation should be repeated. If the process continues to fail, more substantial changes to the process may be appropriate.

Class A: Monitoring for Fecal Coliform or Salmonella sp. *Densities*

Part 503 requires that, to qualify as a Class A sludge, sewage sludge must be monitored for fecal coliform or *Salmonella* sp. and have a density of less than 1,000 MPN fecal coliform per gram of total solids sewage sludge (dry weight basis) or *Salmonella* sp. densities below detection limits (3 MPN/4 g). The regulation does not specify the number of samples that have to be taken during a monitoring event. One sample is not enough to properly represent the sewage sludge. It is recommended that multiple

Table 10-1. True Geometric Mean Needed If Standard Fecal Coliform Density of 2 Million CFU Per Gram is to be Rarely Exceeded

Assumptions

- The fecal coliform densities of the sewage sludge are log normally distributed. (The arithmetic mean of the logarithms of the fecal coliform densities is the mean of the distribution. The geometric mean is the antilog of the arithmetic mean of the log values.)
- The goal is to ensure that the measured mean value does not exceed the density requirement more than once in 20 monitoring events.
- The standard deviation of the log density is 0.30.

Calculation

To predict the expected frequency of a measurement using the normal probability distribution, the variable x is converted to the standard measure (u - see below) and its probability of occurrence is obtained from tabulated values of the probability distribution. In this case, the reverse is carried out. A certain probability of occurrence is desired and the value of the standard measure is read from the tables. From the normal distribution table (single-sided), u is 1.645 when P = 0.05 (one in 20),

Where:
P = the proportion of the area under the curve to the right of u relative to the whole area under the curve.
and:
$u = (\bar{x} - \mu)/S_{\bar{x}}$ (Equation 1)
Where:
μ = true log mean
$\bar{x}$ = log mean of the measurements
$S_{\bar{x}} = s/n^{1/2}$
n = number of measurements that are averaged
s = standard deviation of a single measurement of log mean density

The logarithm of the fecal coliform density requirement (2 million CFU/g) is $\bar{x}$ ($\bar{x}$ = 6.301). This is the number that should not be exceeded more than once in 20 monitoring episodes. Substituting into Equation 1 and calculating μ,

$1.645 = (6.301-\mu)/(0.3/7^{1/2})$
$\mu = 6.114$
Antilog 6.114 = 1.3 million CFU/g.

samples (≥7) be taken over a period of two weeks in order to adequately represent sludge quality. Based on the reliability of the treatment process and historic test results, there may be time when a reduction in this monitoring recommendation is justified. In the case of Class A, analytical results from multiple samples are not averaged together; instead, all results must be in compliance with Class A limits.

The measured fecal coliform density provides an estimate of the likelihood of *Salmonella* sp. detection and, if detected, the expected density. Yanko (1987) obtained a good correlation between fecal coliform density and *Salmonella* sp. detections in his extensive investigation of composts derived from sewage sludge. The fraction detected is less than 10% when fecal coliform density is less than 1,000 MPN/g. Yanko also obtained a good correlation between fecal coliform density and *Salmonella* sp. density for those samples for which *Salmonella* sp. were detected. That correlation predicts that, for fecal coliform densities less than 1,000 MPN/g,*Sa/mone//a* sp. densities will be less than 1.0 MPN/g. Thus, at fecal coliform densities 4,000 MPN/g, *Salmonella* sp. detections will be infrequent and, if detected, densities are expected to be below 1 MPN/g.

The Part 503 a!lows the monitoring of either fecal coliform or *Salmonella* sp. in order to demonstrate compliance with Class A microbiological requirements. The *Salmonella* sp. determination is somewhat similar to the fecal coliform test, but it is much more expensive and requires a high experience level. In all likelihood, the *Salmonella* sp. tests would have to be carried out by a contract laboratory.

The standard deviation for Class A sludges will most likely be lower than for Class B. This is due to the fact that we have many more organisms present in Class B sludges which are not equally distributed within the biosolids. Therefore you have greater variability and hence a higher S.D.

What action to take to further reduce pathogens in case the fecal coliform requirement is not met depends on the process. In general, verification of retention times and temperatures as well as elimination of cross-contamination between feed and treated sludge or opportunities for reintroduction of pathogens into treated sludge are recommended. For aerated deep-pile composting, thicker insulating layers on the pile and longer maturing times are suggested.

Class A: Monitoring for and Demonstration of Enteric Virus and Viable Helminth Ova Reduction

The accuracy of monitoring results demonstrating the absence of enteric viruses and helminth ova is influenced by the variability in the influent to the treatment works and the inherent error in the experimental method. Information

on method error for both enteric viruses and helminth ova is available only on standard deviations calculated from duplicate samples. Goyal et al. (1984) report that, in their comparison of methods for determining enteroviruses, the log standard deviation for the virus determination in sewage sludge was 0.26 (47 degrees of freedom). A review of the work of Reimers et al. (1989) indicates that, in the range of 5 to 100 viable Ascaris ova per 10 grams sewage sludge solids, standard deviation was about half the number of viable ova. This is equivalent to a log density of 0.3, which is about the same as for fecal coliform. Thus, there is no unusually high variability in the basic test methods that would require an increased number of samples to minimize this effect.

Deciding how many samples to take for enteric viruses and viable helminth ova is more difficult than for fecal coliform and *Salmonella* sp. because enteric viruses and viable helminth ova often may not be present in untreated sludge. For this reason, the interpretation of the density determinations for these organisms in treated sludge depends on the quality of the feed sludge. If no enteric viruses or viable helminth ova are detected in the feed sludge, then the absence of these organisms in corresponding samples of treated sludge does not indicate in any way whether the process is or is not capable of reducing these organisms to below detectable limits. The ability of a process to reduce these organisms to below detectable limits is indicated when analysis shows that these organisms were present in the feed sludge and were not present in corresponding samples of treated sludge. One important questions is: What fraction of the total pairs of corresponding samples must show positive in the feed sludge and negative in the treated sludge to provide convincing evidence that the process consistently reduces enteric viruses and viable helminth ova to below detectable levels? This is a difficult question to answer.

Because viable helminth ova are relatively stable microorganisms, compositing is suggested as a way to obtain meaningful representative samples and analytical results. If precautions are taken, such as cooling the sample promptly to close to 0°C (32°F) and destroying or neutralizing any added chemicals such as strong bases that were added as part of the pathogen-reducing process, composites can be collected over a 2-week period. Corresponding composites of feed and treated sludge can be compared, with a much lower likelihood of not finding viable helminth ova in the feed sewage sludge. Because the analytical method itself has a high variance (see above), a minimum of four duplicates of the composite should be tested.

For enteric viruses, the same approach may be used as suggested above for viable helminth ova. Precautions are taken to cool the sample and destroy or neutralize any chemicals added in the pathogen-reducing process. Samples are collected on separate days and are promptly frozen at 0°F (-18°C), or -94°F (-70°C) if samples will be stored for more than 2 weeks. When the samples are to be analyzed, the individual samples are thawed and composited, and viral densities determined.

The density of both viable helminth ova and enteric viruses in processed sludge must be based on the results of several measurements. Most of these measurements are expected to show below detectable densities. If any one sample is above 1 PFU (for viruses) or 1 viable helminth ovum (for helminths) per 4 grams, the process does not meet the Part 503 operational standard.

Vector Attraction Reduction Tests

Reduction in Volatile Solids

One way to demonstrate reduction in volatile solids requires measurement of volatile solids of the sewage sludge before and after sludge treatment. The sampling point for the "after treatment" measurement can be immediately leaving the processing unit or at the point of use or disposal, provided there has been no significant dilution downstream with inert solids.

Farrell et al. (1996) have determined the standard deviation of the percent volatile solids (%VS) determination for separate samples withdrawn from pilot-scale digesters to be 0.65% (total solids content ranged from 2% to 5%). Conventional statistical procedures (see Davies and Goldsmith, 1972) were used to calculate the standard error of the percent volatile solids reduction (%VSR), which is calculated from the %VS of the untreated and treated sludge. The standard error of the %VSR when calculated by the Van Kleeck equation (see Appendix D) is 2.0% in the range of interest (38% VSR). The 95% confidence limits of the %VSR are ±4%, which is excessive. If the %VSR is the average of seven determinations, the confidence interval is reduced to ±1.5%, which is a more acceptable value.

The most difficult problem with the %VSR determination, as discussed above in Section 10.4, is getting correspondence of the influent sludge with the effluent sludge. If there has been a significant change in an inlet concentration or flow rate, achieving correspondence can require several months of monitoring inlet and outlet volatile solids concentrations. If conditions have been steady and feed compositions have been fluctuating about an average value for a long period, data taken over a 2-week period would be adequate to establish steady state performance.[1] This implies that data have been collected beforehand that demonstrate that sewage sludge composition has reached steady state for a long period before the 2-week sampling period. It appears that regular collection of data for some months before the sampling period is unavoidable to demonstrate steady state performance before the testing period. Fortunately, the total and volatile solids determinations are not costly, and they provide valuable operating information as well.

Total and volatile solids content of a sample do not change significantly over the course of a day, particularly if

[1]Note that, unlike the plug flow case, there should be no displacement in time between comparisons of input and output for fully mixed reactors. Only when there has been a significant change is it necessary to wait a long time before the comparisons can be made.

the sludge is cooled. Time composites collected over a course of a day can be used for these determinations. Seven or more determinations are recommended to reduce the error band around the mean to minimize the chance that a process that actually has a greater volatile solids reduction than 38% might show an average that is below this value.

Additional Digestion Tests

The essential measurement in the additional digestion tests for aerobic and anaerobic sludges (see Sections 8.3 and 8.4) is the percent volatile solids content (%VS) from which the percent volatile solids reduction is calculated (%VSR). Using the standard deviation of 0.65% determined by Farrell et al. (see above), the standard error of the %VSR when calculated by the Van Kleeck equation (see Appendix D) is 2.5% in the range of interest (15% VSR). The 95% confidence limits of the %VSR are ± 5%. The tests (see Appendix D) require substantial internal replication which shrinks these confidence limits. Samples should also be taken to account for the variability in the process. The 2-week sampling period suggested for the Class A disinfection microbiological tests may be excessively restrictive if several samples are to be evaluated. The equipment needed for the test is not expensive but the units take up substantial bench space. It is unlikely that a treatment works will want to have more than two sets of test equipment. Since the tests take 30 to 40 days, it is not possible to run more than one set of tests (two in a set) within a monitoring event. It is suggested that these tests be routinely carried out during the year and the results be considered applicable to the monitoring period. It is estimated on a best judgment basis that five tests are needed to account for variability in the feed sludge and in the treatment process itself.

Specific Oxygen Uptake Rate Test

The Oxygen uptake measuring part of the specific oxygen uptake rate test (SOUR, see Appendix D) can be completed in the laboratory or field in a few minutes, so there is no difficulty in completing the test during a monitoring event. The test requires the SOUR determination to be made on two subsamples of a given sample. Farrell et al. (1996) found that, in the target SOUR value of 1.5 mg O_2/hr/g, sludge solids replicates agreed within about ± 0.1 mg O_2/hr/g. Since the test is easy to run, it is suggested that seven tests within the 2-week sampling event will adequately define the SOUR. Labs performing this test should demonstrate that they too can achieve this level of precision for replicates (±0.1 mg O_2/hr/g). Arithmetic average of the tests should be computed and compared against the Part 503 SOUR value.

Raising the pH to 12

There are two options in the regulation that reduce vector attraction by pH adjustment. In the first, sludge is raised in pH by alkali addition so that pH is ≥12 for 2 hours after alkali addition and, without further alkali addition, remains at pH ≥11.5 for an additional 22 hours (see Section 8.7). The second method is for domestic septage. The pH is raised to pH ≥12 by alkali addition and, without further addition of alkali, remains at ≥12 for 30 minutes (see Section 8.13). As noted in Section 5.6, the term alkali is used in the broad sense to mean any substance that increases pH.

The pH requirement in the regulation was established using data obtained at room temperature (Counts and Shuckrow, 1975; Ronner and Cliver, 1987), which is presumed to have been 25°C (77°F). Consequently, pH should be measured at 25°C (77°F) or measured at the existing temperature and converted to 25°C (77°F) by use of a temperature-versus-pH conversion table determined experimentally for a treated sludge that meets the pH requirements. The correction is not trivial for alkaline solutions; it is about -0.03 pH units/°C (-0.017 pH units/°F) for aqueous calcium hydroxide with a pH of about 12, and should not be ignored. Note that temperature-compensated pH meters only adjust instrument parameters and do not compensate for the effect of temperature on the pH of the solution.

pH Adjustment and Septage

Each container of domestic septage being treated with alkali addition must be monitored. The pH is monitored just after alkali addition and a half hour or more after alkali addition. Bonner and Cliver (1987) suggest that alkali (they used slaked lime) be added to the septic tank or to the septic tank truck while domestic septage is being pumped from a septic tank into the tank truck. If slaked lime is used, a dose of 0.35 lb per 10 gallons (4.2 g per liter) is sufficient to raise the pH to 12 for a typical domestic septage of about 1% solids content. The agitation from the high velocity incoming stream of septage distributes the lime and mixes it with the domestic septage. The pH is measured when the truck loading is complete. The truck then moves to the use or disposal site. Agitation generated by the motion of the truck may help in mixing and distributing the lime however, supplemental mixing in the tank may be needed. The pH is again measured at the use or disposal site. The second pH measurement should be at least a half hour after the addition of lime. The sample may be obtained through the top entry of the tank truck, using, for example, a stainless steel cup welded to a long handle to collect the sample. The pH is most conveniently measured with alkaline pH paper in the pH range of 11 to 13. The pH paper can age and become contaminated. It is best to use strips from two separate containers. If they do not agree, compare with a third batch and reject the one that disagrees with the others. Accuracy of these measurements is within ± 0.1 pH unit. If the pH is below 12, either initially or after 30 minutes, more lime should be added and mixed in. After an additional waiting period of at least 30 minutes, the pH must again be measured to ensure that it is greater than 12.

pH Adjustment and Sewage Sludges

For addition of alkali to sewage sludges, the pH requirement is part of both the PSRP process description (see Section 5.3) and the requirement of a vector attraction option (see Section 8.7). Monitoring is required from 1 to 12 times a year (see Table 3-4 in Chapter 3), and the pro-

cess must meet the prescribed operating conditions throughout the year.

Alkali is sometimes added to liquid sludge and sometimes to dewatered sludge. The pH requirements as stated in the regulation apply in the same way for both liquid and dewatered sludge. For the first measurement of pH in liquid sludge 2 hours after addition of alkali, it is assumed that the alkali and the sludge have been mixed together for a sufficient time to reach equilibrium (not considering the gradual changes that occur over substantial periods of time). Consequently, the pH measurement can be made directly in the liquid sludge. The pH measurement is made preferably with a pH meter equipped with a temperature compensation adjustment and a low-sodium glass electrode for use at pH values over 10. The pH electrode is inserted directly in the sludge for the reading. The second measurement is made 24 hours after addition of alkali. If the sludge is still in the liquid state, the pH measurement is made in the same fashion. However, if the process includes a dewatering step immediately following the alkali addition and the sludge is now a dewatered cake, the cake must be made into a slurry for the pH measurement. Acceptable procedures for preparing the sample and measuring pH are given by EPA (1986). The procedure requires adding 20 mL of distilled water (containing 0.01 M $CaCl_2$) to 10 g of sludge cake, mixing occasionally for half an hour, waiting for the sample to clarify if necessary, and then measuring pH. The important step is the mixing step that allows the alkali-treated dewatered sludge to come into equilibrium with the added water.

Number of Samples

The accuracy of pH meters and of pH paper is within ± 0.1 pH unit. More than one sample is necessary if the domestic septage or sludge is not well mixed. If the lime has been added gradually over the period in which septage is being pumped into a tank truck is considered adequate and a single measurement taken at the top of the tank truck is sufficient. If alkali has been added to liquid sludge in a tank at a treatment plant, tests are easily run to establish how much mixing is required to produce a uniform pH in the sludge. If this adequate mixing time is used, a single sample withdrawn from the tank for pH measurement is sufficient.

If alkali is added to sludge cake, more sampling is suggested. Typically, alkali (usually lime) is added to sludge cake in a continuous process. The sludge from the dewatering process discharges continuously to a mixer, from which it discharges to a pile or to a storage bin. Lime is metered into the mixer in proportion to the sludge flow rate. The flow rate and compositions of the sewage sludge can vary with time. To demonstrate compliance on a given day, several time-composite samples each covering about 5 minutes should be collected, and the pH measured. This procedure should be repeated several times during the course of a 2-week sampling event.

For sludge cake, the composites collected for pH measurement must be reduced in size for the pH measurement. The alkaline-treated sludge may be discharged from the mixing devices in the form of irregular balls that can be up to 5 to 7.6 cm (2 or 3 inches) in diameter. It is important that the biosolids to which the environment will be exposed have been treated to reduce pathogens and vector attraction to the desired level. If the discharged biosolids are ball shaped and the alkali has not penetrated the entire ball, one or both of these goals is not met for the material inside the ball. The entire ball should be at the proper pH. It is suggested that the composite be thoroughly mixed and that a subsample be taken for analysis from the mixed composite. An even more conservative approach is to sample only the interior of the balls.

Percent Solids Greater Than or Equal to 75% and 90%

The monitoring requirement for these vector attraction options (see Sections 8.8 and 8.9) is simply measurement of total solids. This measurement is described in Standard Methods (APHA [1992], Standard Method 2540 G). Standard Methods states that duplicates should agree within ± 0.5% of their average. For 75% solids, this would be ± 3.8%. For a continuous process, a time-composite sample can be taken over the course of a day, and duplicate analyses carried out on this composite. This is possible because biological activity essentially ceases at high solids content, and decomposition will not occur. Approximately seven such composites over the course of a 2-week sampling period would provide adequate sampling.

Some drying processes such as drying sludge on sand drying beds are batch processes. In such cases, it may be desirable to ascertain that the sludge meets the vector attraction reduction requirements before removing the sludge from the drying area. This can be done by taking two separate space-composites from the dried sludge, analyzing each of them in duplicate, and removing the sludge only if it meets the required solids content.

Frequently Asked Questions

How many samples should be submitted for each monitoring event for Class A pathogen tests? How many grab samples should be taken for each composite?

The 503 regulations do not specify a minimum number of samples per sampling event for Class A sludge, but it is strongly recommended that enough samples be taken to adequately represent the mass of material which is to be distributed. A minimum of seven samples, as required for Class B fecal coliform testing is recommended, but the number of samples, and the number of grab samples which each composite should represent, depends on the size of the facility and the volume of sludge product that is distributed. A sampling plan should be developed and submitted to the permitting authority for review.

Are you out of compliance for Class A if you take more than one sample, and one result is over the limit?

Yes, In order to meet Class A standards, all material must meet pathogen standards. Although Class B pathogen standards are based on a geometric mean of analytical results, geometric (or arithmetic) means are not acceptable for compliance with Class A standards. Therefore, if several samples are submitted for analysis during one monitoring event, and one sample is found to be out of compliance with Class A pathogen standards, the entire batch must be considered Class B (assuming it meets Class B standards).

For batch processes, one way to prevent one 'out of compliance' sample from affecting the classification of a large volume of finished product is to maintain smaller separate storage piles and to sample from segregated areas. For example, finished compost could be separated into piles based on when composting was completed. If one result shows non-compliance with the Class A standards, but other samples are within the Class A limits, it would be relatively simple to separate out the non-compliance material and reprocess it or distribute it as Class B material.

Continuous flow operations can reduce the probability that one outlying result will cause their process to fail by taking multiple samples over a 24-hour period and compositing the samples. The composite sample can then be analyzed in duplicate to provide more data.

Averaging lab results is allowable as a means to eliminate laboratory variability; however, all data must be reported to the permitting authority for review. For example, if a lab runs duplicate fecal coliform analyses on one sample, the results from these analyses can be averaged together for one result. This is not intended to allow facilities to rerun analyses on out-of-compliance samples in the hope of lowering average results.

Pathogen testing on our Class A sludge product has shown that we consistently reduce *Salmonella* sp. to below detectable limits, but fecal coliform levels are sometimes over 1000 MPN per gram. Should we be concerned about this? Should we be concerned if the fecal coliform level in our Class A material is occasionally as high as 990 MPN/gram?

According to the regulations, neither situation is a problem. You are required to comply with either the *Salmonella* sp. or the fecal coliform standards, not both. However, the level of fecal coliform in the product may indicate that there is incomplete pathogen destruction or some regrowth in your product, in which case you should examine your pathogen and vector attraction reduction processes to ensure that you are complying fully with the requirements and are not contaminating the product. The high fecal coliform counts may also be due to the presence of other, non-fecal coliforms in the sludge. These coliforms, which share some characteristics with fecal coliforms, may be detected in fecal coliform testing. They are particularly likely to appear in compost samples since they tend to be found in woody materials.

In addition, certain processes have been found to leave a residual population of fecal coliform which can repopulate the sludge. It is possible that testing would find fecal coliform over the Class A limits even when the pathogenic bacteria for which fecal coliform are intended to serve as indicators have been reduced below detectable levels. Composting and lime treatment are two of these processes. It is therefore recommended that if properly operated Class A facilities yield high populations of fecal coliform in finished solids that *Salmonella* sp. be used as the indicator organism for these types of facilities.

Can we distribute finished material before getting pathogen test results back? If yes, what do you do if results later show that material was not Class A?

This issue is covered extensively in Section 4.10. Sludge classification is based on the most recent available lab data, and therefore, material generated during a sampling period can be distributed before results from that sampling period are available (based on the results of the previous sampling event). However, it is recommended that materials generated during the sampling period be held on site until results are available in order to prevent a situation in which material is erroneously classified and distributed as Class A.

If composting piles are monitored for temperatures at three different points, do all three points have to meet PFRP at the same time?

All particles of sludge must undergo the PFRP time and temperature regime. For aerated static pile and in-vessel composting, the entire pile must meet the temperature requirements concurrently. If one point is found to be below the 55°C level during the temperature monitoring period, the entire pile is considered to be out of compliance, and the three consecutive day PFRP period must start over again. However, if temperatures are taken in distinct piles or cells of an in-vessel system, each section can meet the PFRP requirements separately.

Our facility often stockpiles composted sewage sludge over the winter. In the spring, we may have as much as four months' production of compost on site. How should sampling be conducted?

After material is stored on site, it must be resampled in order to determine if regrowth of pathogens has taken place. The number of samples should correspond to the time period that the stockpile represents and the mandated frequency of sampling based on the facility's size. For example, if a facility is required to sample sludge every month, and there are four months' worth of compost on site, a minimum of four samples (therefore, 4 times 7 or 28 analysis) from appropriate sections of the stockpile must be submitted. Ideally, material will be stored in segregated piles so that each month's production of compost can be sampled separately.

This applies to other long-term sludge storage such as lagoons. The number of samples taken from lagoons should be based on the time period that the lagoon(s) repre-

sent and the frequency of sampling that a facility is obligated to follow because of the rate of sludge generation.

What should we do if our process changes or expands?

Permits are granted based on particular operational parameters. Therefore, any projected changes in the operation or expanded flow should be discussed with the permitting authority before changes are made, even if you do not have a permit.

Can we be permitted for operation only during certain months?

If your operation will only meet pathogen or vector attraction reduction standards during part of the year, your permit can contain conditions which allow distribution only during these times. Permits can also be written to take ambient conditions into account; for example, some "low-impact" composting facilities are required to retain material over two summers. It may also be practical to limit storage and utilization of particular types of sludges to some seasons.

Can we combine two PSRP processes that individually do not meet the specified process requirements to produce a Class B product? Can time in extended aeration be added to digester time?

The only way to evaluate the effectiveness of pathogen reduction through a combination of two or more PSRP processes is by testing the sludge for fecal coliform density. If sufficient pathogen reduction can be demonstrated consistently, the preparer also may consider applying for a PSRP equivalency for the combined processes in order to eliminate the need for fecal coliform testing.

In general, extended aeration cannot be considered a PSRP or part of a PSRP because raw sewage is continually being added to the aerator and blending with the mixed liquor. Specific cases in which extended aeration is not subject to short-circuiting and is thought to contribute significantly to the pathogen reduction process should be evaluated by testing the resulting sludge for fecal coliform density and by the SOUR test or extended aerobic digestion one for addressing VAR requirements.

If I produce an "exceptional quality" (EQ) product and mix the product with topsoil before distribution, does the mix have to be tested for 503 compliance?

Regulations regarding "exceptional quality" material, or material which complies with the highest levels of pathogen and vector attraction reduction as well as heavy metals limits, are based on when the sludge preparer loses control of the material. If the EQ material is still within your control (i.e. on-site or owned by the preparer) when it is mixed, the new product must undergo pathogen and vector attraction reduction processes and be analyzed for Part 503 parameters including pathogens, vector attraction reduction, and heavy metals. This may be problematic for some facilities since a mix of stable compost and soil, for example, is unlikely to meet/undergo PFRP time and temperature requirements. You may have to test the mix for helminth ova and enteric viruses in order to demonstrate compliance with Class A pathogen reduction. If, however, the EQ material has left your control (i.e. is sold to a soil blender), the material falls out of the jurisdiction of the Part 503, and any subsequent blending of the material with other products is not covered by these regulations. Non-EQ materials are always subject to the Part 503, and storage or mixing of non-EQ materials with soil, yard waste, or other additives must be followed with re-testing and re-classification. The party responsible for the sludge mixing is considered a sludge preparer and is therefore subject to all Part 503 requirements.

Our sludge product meets vector attraction reduction requirements because the level of total solids in the material is greater than 75 percent. If stored material becomes wet because of rainfall, is the material still in compliance with the requirements?

The vector attraction reduction requirement stipulates that the material be processed to greater than 75 percent (or 90 percent when unstabilized solids are present) total solids. If dried sewage sludge (biosolids) is stored at your facility and becomes wet, it still meets the vector attraction reduction criteria as long as the facility has testing documentation that the biosolids were processed to ≥75 or 90 percent solids prior to the time the material became wet. It is a good management practice however to prevent dried biosolids from getting wet while it is being stored at the facility.

In the case of vector attraction reduction Option 6, it is required that the pH of the sludge be raised to ≥12 for 2 hours and ≥11.5 for 22 hours. It is not required that the sludge be maintained at the elevated pH once the material has fulfilled the vector attraction reduction requirement. However, it is important to note that the sludge which appears to be stable under the elevated conditions may become odorous and attract vectors if the pH declines. It is recommended that sludge be utilized before the pH drops below 10.5 in order to prevent odors or vector attraction which may result in a public nuisance.

Can Alternative 1 be used to demonstrate pathogen reduction for composting if the compost piles do not attain 55°C for 3 consecutive days?

Alternative 1 is based on similar time/temperature relationships as the composting process. Regime A ($D=131{,}700{,}000/10^{0.1400t}$ in which $t \geq 50°C$ and $D \geq 0.0139$ days) can apply to composting. The table below shows some points on the time/temperature curve that would comply with the regime.

Time (Days)	Temperature (°C)
0.02 (30 min)	70
0.04 (1 hour)	68
0.08 (2 hours)	66
1	58
2	56
3	55

As shown, it is theoretically possible that a compost pile could comply with Alternative 1 by reaching very high temperatures for a short period of time. **Alternative 1 is based on the assumption that all particles of sludge are attaining these temperatures uniformly.** This may be difficult in a compost pile unless the compost pile is completely enclosed and well insulted. In addition, excessive temperatures in a composting process may result in anaerobic conditions and subsequent odors.

Our facility is planning to expand next year, and we would like to implement a new process for pathogen reduction. We will submit our request for equivalency to the PEC this year, but, given the current turn around time for applications, do not expect to have equivalency granted for 2 more years. What should we do in the interim?

Depending on the class of sludge you are hoping to produce, you have two options. If you are producing a Class B sludge, you should continue to do fecal coliform testing in order to demonstrate compliance with the Class B limit of 2 million CFU or MPN per dry gram of sludge. If you are producing a Class A sludge, you could follow Alternative 4 and test the sludge product for helminth ova and enteric viruses as well as either fecal coliform or *Salmonella* sp. In either case, an application for equivalency will require data demonstrating pathogen reduction, so this data will be useful in that respect.

You may also wish, in the case of Class A sludge, to test the feed sludge for enteric virus and helminth ova. Adequate demonstration that the process reduces these pathogens on a consistent basis may qualify the process as a PFRP equivalent one (Class A, Alternative 6). You should consult with the permitting authority to determine an acceptable sampling protocol. Demonstration of helminth ova and virus reduction is difficult, particularly if the density of these pathogens in the influent is low or sporadic. The sampling program must demonstrate that actual reduction is taking place, not just that the pathogen density in the treated sludge is low. Once pathogen reduction has been sufficiently demonstrated, testing for enteric viruses and helminth ova are no longer necessary as long as the process is conducted in compliance with specified conditions for PFRP equivalency.

Our facility distributes Class B lime stabilized sludge to farmers who use the sludge on a variety of crops. Is it our responsibility to keep track of how this sludge is used?

You are required to provide the farmers with all sludge quality data as well as regulatory information which will allow them to comply with the appropriate site restrictions. The applicator, and/or the POTW, is then responsible for following the correct site and harvest restrictions. However, given that any problems with land application will most likely affect the public perception of sludge reuse and this may in turn affect your facility, it is recommended that you work closely with farmers to ensure that the regulations are being followed. In addition, the permitting authority may choose to include conditions related to site and harvest restrictions in your permit.

Is there any limit of how long Class B sludge can be stored before it is used?

Part 503 Rule defines storage as "the placement of sewage sludge: on land on which the sewage sludge remains for two years or less." It does not include placement of sewage sludge on the land for treatment. After two years the storage site is considered a final disposal one. The permitting authority may include storage conditions in your permit which mandates usage of the material while it still retains certain characteristics (moisture content) or within a certain time period. It is recommended that storage of Class B material be limited to 30 days and be conducted under similar site restrictions as usage of Class B material. For example, public contact and access to the storage site should be restricted.

If the vector attraction reduction requirements have been fulfilled under Option 6, is there any need for the sludge to remain at an elevated pH?

In the case of vector attraction reduction Option 6, it is required that the pH of the sludge be raised to ≥12 for 2 hours and ≥11.5 for 22 hours. It is not required that the sludge be maintained at the elevated pH once the material has fulfilled the vector attraction reduction requirement. However, it is important to note that sludge that appears to be stable under the elevated conditions may become odorous and attract vectors if the pH declines. It is recommended that sludge be utilized before the pH drops below 10.5 in order to prevent odors or vector attraction that may result in a public nuisance.

Chapter 11
Role of EPA's Pathogen Equivalency Committee in Providing Guidance Under Part 503

11.1 Introduction

One way to meet the pathogen reduction requirements of the Part 503 is to treat sewage sludge in a process "equivalent to" the PFRP or PSRP processes listed in Appendix B of the Part 503 regulation (see Tables 4-2 and 5-1 for a list of these processes):

- Under Class A Alternative 6, sewage sludge that is treated in a process equivalent to PFRP and meets the Class A microbiological requirement (see Section 4.3) is considered to be a Class A biosolids with respect to pathogens (see Section 4.9).

- Under Class B Alternative 3, sewage sludge treated by a process equivalent to PSRP is considered to be a Class B biosolids with respect to pathogens (see Section 5.4).

These alternatives provide continuity with the Part 257 regulation, which required that sewage sludge be treated by a PSRP, PFRP, or equivalent process prior to use or disposal. There is one major difference between Part 257 and Part 503 with respect to equivalency. Under Part 257, a process had to be found equivalent in terms of both pathogen reduction and vector attraction reduction. Under Part 503, equivalency pertains only to pathogen reduction. However, like all Class A and B biosolids, sewage sludges treated by equivalent processes must also meet a separate vector attraction reduction requirement (see Chapter 8).

What Constitutes Equivalency?

To be equivalent, a treatment process must be able to consistently reduce pathogens to levels comparable to the reduction achieved by the listed PSRPs or PFRPs. (These levels, described in Section 11.3, are the same levels required of all Class A and B biosolids.) The process continues to be equivalent as long as it is operated under the same conditions (e.g., time, temperature, pH) that produced the required reductions. Equivalency may be site-specific; equivalency applies only to that particular operation run at that location under the specified conditions, and cannot be assumed for the same process performed at a different location, or for any modification of the process. Processes that are able to consistently produce the required pathogen reductions under the variety of conditions that may be encountered at different locations across the country may qualify for a recommendation of national equivalency (a recommendation that the process will be equivalent wherever it is operated in the United States).

Who Determines Equivalency?

The permitting authority is responsible for determining equivalency under Part 503. The permitting authority and facilities are encouraged to seek guidance from EPA's Pathogen Equivalency Committee (PEC) in making equivalency determinations. The PEC makes both site-specific and national equivalency recommendations.

What Are the Benefits of Equivalency?

A determination of equivalency can be beneficial to a facility, because it reduces the microbiological monitoring burden in exchange for greater monitoring of process parameters. For example a facility meeting Class A requirements by sampling for enteric viruses and viable helminth ova in compliance with Alternative 4 may be able to eliminate this monitoring burden if they are able to demonstrate that their treatment process adequately reduces these pathogens on a consistent basis[1]. Similarly, a facility meeting Class B Alternative 1 requirements by analyzing sewage sludge for fecal coliform may be able to eliminate the need for testing if the process is shown to reduce pathogens to the same extent as all PSRP processes. Equivalency is also beneficial to facilities which may have low cost, low technology systems capable of reducing pathogen populations. Options such as long-term storage, air drying, or low technology composting have been considered by the PEC.

Because equivalency status allows a facility to eliminate or reduce microbiological sampling, it is imperative that the treatment processes deemed equivalent undergo rigorous review to ensure that the Part 503 requirements are met. Obtaining a recommendation of equivalency necessitates a thorough examination of the process and an ex-

[1]A determination of PFRP equivalency will not reduce the monitoring required for *Salmonella* sp. or fecal coliform because all Class A biosolids, even biosolids produced by equivalent processes, must be monitored for *Salmonella* sp. or fecal coliform (see Section 4.3).

tensive sampling and monitoring program. The time needed to review an application is contingent on the completeness of the initial application. Sewage sludge preparers wishing to apply for equivalency should review this chapter carefully and discuss the issue with the regulatory authority in order to determine if equivalency is appropriate for their situation.

Figure 11-1 indicates when application for equivalency may be appropriate.

Recommendation of National Equivalency

The PEC can also recommend that a process be considered equivalent on a national level if the PEC finds that the process consistently produces the required pathogen reductions under the variety of conditions that may be encountered at different locations across the country. A recommendation of national equivalency can be useful for treatment processes that will be marketed, sold, or used at different locations in the United States. Such a recom-

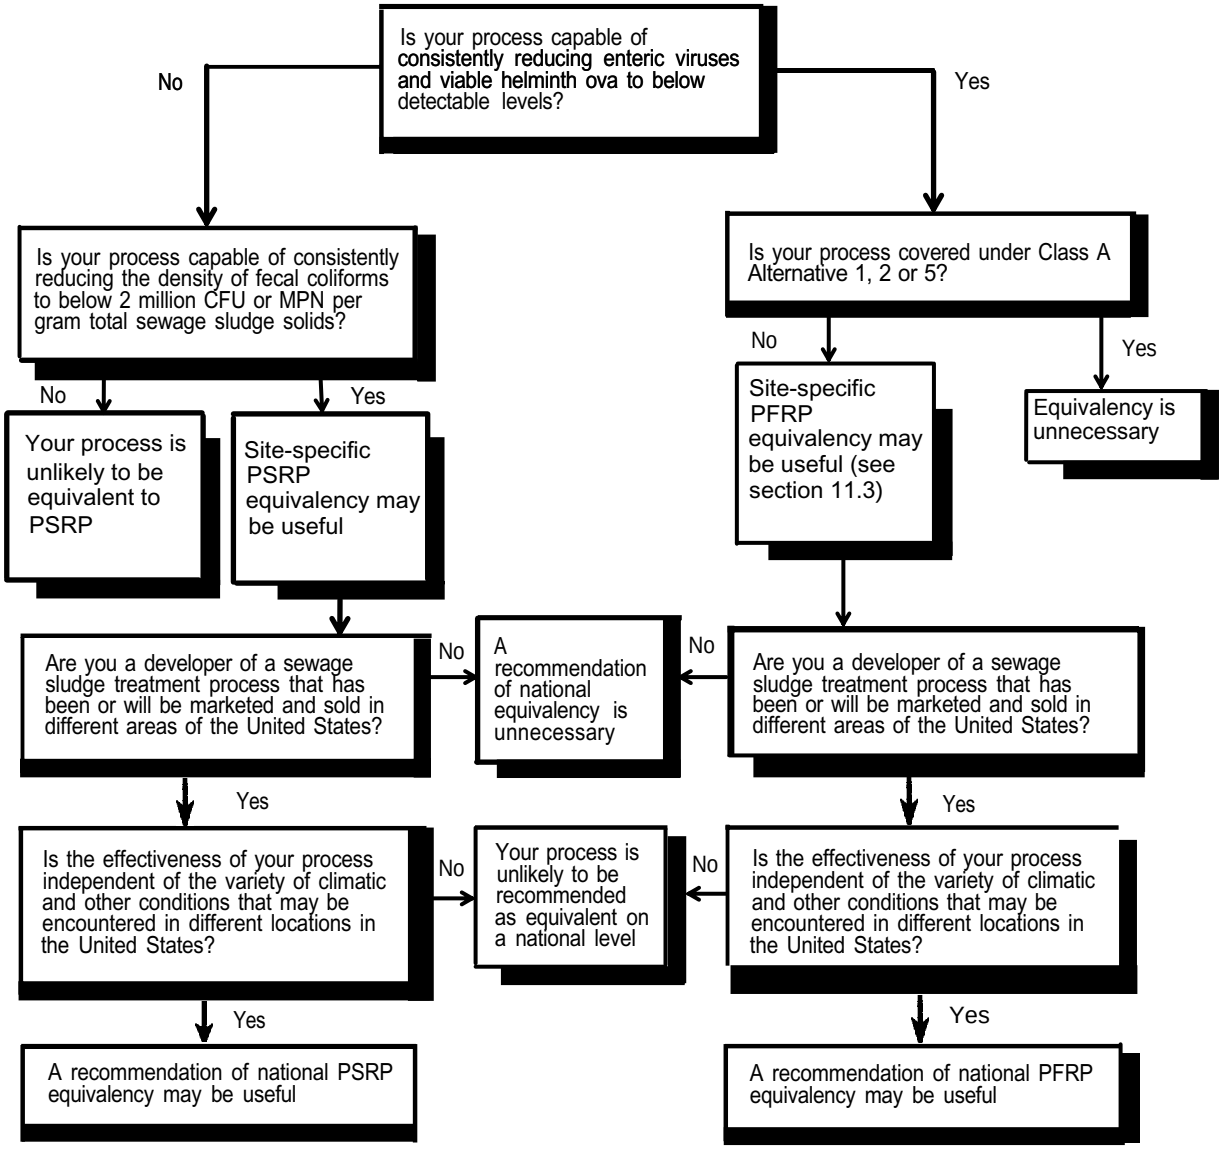

Figure 11-1. When is application for PFRP or PSRP equivalency appropriate?

Item E 000677

mendation may be useful in getting PFRP or PSRP equivalency determinations from different permitting authorities across the country.

Role of the Pathogen Equivalency Committee

The U.S. Environmental Protection Agency created the Pathogen Equivalency Committee (PEC) in 1985 to make recommendations to EPA management on applications for PSRP and PFRP equivalency under Part 257 (Whittington and Johnson, 1985). The PEC consists of approximately ten members with expertise in bacteriology, virology, parasitology, environmental engineering, medical and veterinary sciences, statistics, and sewage sludge regulations. It includes representatives from EPA's Research and Development Office, the Office of Water, and the regional offices. The 1993 memorandum included at the end of this chapter describes the role of the PEC.

Guidance and Technical Assistance on Equivalency Determinations

The PEC continues to review and make recommendations to EPA management on applications for equivalency under Part 503. Its members also provide guidance to applicants on the data necessary to determine equivalency, and to permitting authorities and members of the regulated community on issues (e.g., sampling and analysis) related to meeting the Subpart D (pathogen and vector attraction reduction) requirements of Part 503. It is not necessary to consult the PEC with regard to sampling and monitoring programs if a protocol is already approved under one of the Class A alternatives. Figure 11-2 elaborates on the role of the PEC under Part 503.

What's in This Chapter?

This chapter explains how the PEC makes equivalency recommendations and describes how to apply for PEC guidance. The guidance in this chapter may also prove useful for permitting authorities in establishing the information they will need to make equivalency determinations.

11.2 Overview of the PEC's Equivalency Recommendation Process

The first point of contact for any equivalency determination, recommendation, or other guidance is usually the permitting authority. This is the regional EPA office or the State in cases in which responsibility for the Part 503 program has been delegated to the state. Appendix A provides a list of EPA Regional and state Contacts. If PEC involvement is appropriate, the permitting authority will coordinate contact with the PEC.

The PEC considers each equivalency application on a case-by-case basis. Applicants submit information on sewage sludge characteristics, process characteristics, climate, and other factors that may affect pathogen reduction or process efficiency as described in Section 11.5. The committee evaluates this information in light of current knowledge concerning sewage sludge treatment and pathogen reduction, and recommends one of five decisions about the process or process sequence:

- It is equivalent to PFRP.
- It is not equivalent to PFRP.
- It is equivalent to PSRP.
- It is not equivalent to PSRP.
- Additional data or other information are needed.

Site-specific equivalency is relevant for many applications; to receive a recommendation for national equivalency, the applicant must demonstrate that the process will produce the desired reductions in pathogens under the variety of conditions that may be encountered at different locations across the country. Processes affected by local climatic conditions or that use materials that may vary significantly from one part of the country to another are unlikely to be recommended as equivalent on a national basis unless specific material specifications and process procedure requirements can be identified.

If the PEC recommends that a process is equivalent to a PSRP or PFRP, the operating parameters and any other conditions critical to adequate pathogen reduction are specified in the recommendation. The equivalency recommendation applies only when the process is operated under the specified conditions.

If the PEC finds that it cannot recommend equivalency, the committee provides an explanation for this finding. If additional data are needed, the committee describes what those data are and works with the permitting authority and the applicant, if necessary, to ensure that the appropriate data are gathered in an acceptable manner. The committee then reviews the revised application when the additional data are submitted.

11.3 Basis for PEC Equivalency Recommendations

As mentioned in Section 11.1, to be determined equivalent, a treatment process must consistently and reliably reduce pathogens in sewage sludge to the same levels achievable by the listed PSRPs or PFRPs. The applicant must identify the process operating parameters (e.g., time, temperature, pH) that result in these reductions.

PFRP Equivalency

To be equivalent to a PFRP, a treatment process must be able to consistently reduce sewage sludge pathogens to below detectable limits. For purposes of equivalency, the PEC is concerned only with the ability of a process to demonstrate that enteric viruses and viable helminth ova have been reduced to below detectable limits. This is because Part 503 requires ongoing monitoring of all Class A biosolids for fecal coliform or *Salmonella* sp. (see Section

OFFICE OF WATER

MEMORANDUM

SUBJECT: The Role of the Pathogen Equivalency Committee Under the Part 503 ***Standards for the Use or Disposal of Sewage Sludge***

FROM: **Michael B. Cook, Director**
Office of Wastewater Enforcement & Compliance

James A. Hanlon, Acting Director
Office of Science & Technology

TO: Water Division Directors
Regions I - X

PURPOSE

This memorandum explains the role of the **Pathogen Equivalency Committee (PEC)** in providing technical assistance and recommendations regarding pathogen reduction equivalency in implementing the Part 503 ***Standards for the Use or Disposal of Sewage.*** The PEC is an Agency resource available to assist your permit writers and regulated authorities. This information should be sent to your Regional Sludge Coordinators, Municipal Construction Managers, Permits and Enforcement Coordinators, and Solid Waste Offices, State Sludge Management Agencies and others concerned with sewage sludge management.

BACKGROUND

The PEC Under Part 257

The Criteria for Classification of Solid Waste Facilities and Practices (44 FR 53438, September 13, 1979), in 40 CFR Part 257 required that sewage sludge disposed on the land be treated by either a ***Process to Significantly Reduce Pathogens*** **(PSRP)** or a ***Process to Further Reduce Pathogens (PFRP).*** A list of PSRPs and PFRPs were included in Appendix II to Part 257.

In 1985, the PEC was formed to provide technical assistance and recommendations on whether sewage sludge treatment processes not included in Appendix II to Part 257 were equivalent to PSRP or PFRP. Under Part 257, the PEC provided technical assistance to both the permitting authority and to members of the regulated

Figure 11-2. Role of the PEC under Part 503.

A series of options are provided in the Part 503 regulation for meeting the specific requirements for the two classes of pathogen reduction. One of the Class A alternatives is to treat the sewage sludge by a process equivalent to a PFRP and one of the Class B alternatives is to treat the sewage sludge by a process equivalent to a PSRP. The permitting authority must decide whether a process is equivalent to a PFRP or a PSRP, which is the same approach used under Part 257.

THE PEC UNDER 503

Part 503 provides specific criteria and procedures for evaluating bacterial indicators (Fecal coliforms and ***Salmonella*** sp.), enteric virus and viable helminth ova as well as vector attraction reduction. The PEC will continue to support the permitting authority and members of the regulated community under the new Part 503 regulation in evaluating equivalency situations and providing technical assistance in matters such as sampling and analysis. Specifically the PEC:

- will continue to provide technical assistance to the permitting authority and regulated community, including recommendations to the permitting authority about process equivalency. The PEC also will make both site-specific and national (i.e., a process that is equivalent anywhere in the United States where it is installed and operated) recommendations on *process* equivalency .

- will submit recommendations on process equivalency to the Director, Health and Ecological Criteria Division, Office of Science and Technology, who will review those recommendations and then notify the applicant and appropriate permitting authorities of our recommendation.

For site-specific recommendations, requests for **PEC** review or assistance should be made through the appropriate Federal permitting authority (e.g., the State sludge regulatory authority for delegated programs or the EPA Regional Sludge Coordinator for non-delegated programs). For national recommendations, requests for **PEC** review or assistance can also be made through the Director, Health and Ecological Criteria Division (4304T), Office of Science & Technology, **1200 Pennsylvania Avenue, Washington, DC 20460** or directly to the PEC Chairman. The current **PEC** Chairman is: Dr. James *E.* Smith, Jr., U.S. EPA, NRMRL, (National Risk Management Research Laboratory) 26 W Martin Luther King Dr., Cincinnati, OH 45268 (Tele: 513/569-7355).

Additional information and guidance to supplement the pathogen reduction requirements of Part 503 and the procedures to use to reach the **PEC** and the assistance provided by the PEC is provided in "Control of Pathogens and Vector Attraction in Sewage

Figure 11-2. Role of the PEC under Part 503 (continued).

community. The PEC membership has included representatives from the Office of Research & Development (ORD), Office of Wastewater Enforcement & Compliance (OWEC), and the Office of Science & Technology (OST) with extensive experience in microbiology, sludge process engineering, statistics and regulatory issues. The PEC recommendations regarding the equivalency of processes were forwarded to the Office of Science and Technology, which notified applicants about the PEC's recommendations. Final decisions on equivalency were made by the permitting authority.

The Part 503 Sewage Sludge Standards

The 40 CFR Part 503 Standards for the Use or Disposal of Sewage Sludge were published in the **Federal Register** on February 19, 1993 (58 **FR 9248)** under the authority of section **405** of the Clean Water Act, as amended. Part 503 establishes requirements for sewage sludge applied to the land, placed on a surface disposal site, or fired in a sewage sludge incinerator. Along with the 40 CFR Part 258 Municipal Solid Waste (MSW) Landfill Regulation (56 **FR** 50978, October 9, 1991), which established requirements for materials placed in MSW landfills, the Part 503 requirements for land application of sewage sludge and placement of sewage sludge on a surface disposal site, replaces the requirements for those practices, including the requirement to treat the sewage sludge in either a PSRP or a PFRP, in Part 257.

The Part 503 regulation addresses disease-causing organisms (i.e., pathogens) in sewage sludge by establishing requirements for sewage sludge to be classified either as Class A or Class B with respect to pathogens as an operational standard. Class A requirements are met by treating the sewage sludge to reduce pathogens to below detectable limits, while the Class B requirements rely on a combination of treatment and site restrictions to reduce pathogens. The site restrictions prevent exposure to the pathogens and rely on Natural Environmental processes to reduce the pathogens in the sewage sludge to below detectable levels. In addition to pathogen reduction, a vector attraction reduction requirement has to be met when sewage sludge is applied to the land or placed on a surface disposal site.

Vector attraction reduction requirements are imposed under Part 503 to reduce the potential for spreading of infectious disease agents by vectors (i.e., flies, rodents, and birds). A series of alternative methods for meeting the vector attraction reduction requirement are provided in the rule.

All sewage sludges that are to be sold or given away in a bag or other container for land application, or applied to lawns or home gardens must meet Class A pathogen control and vector attraction reduction requirements. All sewage sludge intended for land application must meet at least the Class B pathogen control and vector attraction reduction requirements. Surface disposal of sewage sludge reguires that Class A or Class B requirements, along with one of the vector attraction reduction practices, be met unless the sewage sludge is covered with soil or other material daily.

Figure 11-2. Role of the PEC under Part 503 (continued).

Sludge" (EPA 625/R-92/013), which will-be updated from **time to time by the PEC. This document is an update of the 1989 document** "Control of Pathogens in Municipal Wastewatsr Sludge" **(EPA/625/l0-89/006),** and is available from CERI.

If there are any questions about this memorandum, **please contact Bob Bastian *from*** OWM **at** 202/564-0635 **or *Dr.* Smith from NRMRL at 513-569-7355..**

Figure 11-2. Role of the PEC under Part 503 (continued).

4.3) to ensure that *Salmonella* sp. are reduced to below detectable limits (i.e., to less than 3 MPN per 4 grams total solids sewage sludge [dry weight basis]) and that growth of pathogenic bacteria has not occurred. Thus, to demonstrate PFRP equivalency, the treatment process must be able to consistently show that enteric viruses and viable helminth ova are below the detectable limits, shown below:

There are two ways these reductions can be demonstrated:

- Direct monitoring of treated and untreated sewage sludge for enteric viruses and viable helminth ova
- Comparison of the operating conditions of the process with the operating conditions of one of the listed PFRPs.

The process comparison approach to demonstrating equivalency is discussed in Section 11.4.

PSRP Equivalency

To be equivalent to PSRPs, a process must consistently reduce the density of pathogenic viruses and bacteria (number per gram of biosolids (dry weight basis)) in mixed sludge from a conventional plant by equal to or greater than 1 log (base 10). Data indicate that, for conventional biological and chemical treatment processes (e.g. ,digestion and lime treatment) a reduction of 1 log (base 10) in pathogenic virus and bacteria density correlates with a reduction of 1 to 2 logs (base 10) in the density of indicator organisms (Farrell et al., 1985, Farrah et al., 1986). On this basis a 2-log (base 10) reduction in fecal indicator density is accepted as satisfying the requirement to reduce pathogen density by 1 log (base 10) for these types of processes (EPA, 1989c). Specifically, the applicant must demonstrate a 2-log (base 10) reduction (number per gram of biosolids (dry weight basis)) in fecal coliforms.

There is substantial data to indicate that sludge produced by conventional wastewater treatment and anaerobic digestion at 35°C for more than 15 days contains fecal coliforms at average log (base 10) densities (number per gram of biosolids (dry weight basis)) of less than 6.0 (Farrell, 1988). Thus, for processes or combinations of processes that do not depart radically from conventional treatment (gravity thickening, anaerobic or aerobic biological treatment, dewatering, air drying and storage of liquid or sludge cake), or for any process where there is a demonstrated correlation between pathogenic bacteria and virus reduction and indicator organisms reduction, the PEC accepts an average log (base 10) density (no./g. TSS) of fecal coliforms and fecal streptococci of less than 6.0 in the treated sludge as indicating adequate viral and bacterial pathogen reduction. (The average log density is the log of the geometric mean of the samples taken. Calculations of average log density should be based on data from approximately nine sludge samples to account for the natural variability and the variability of the microbiological tests.)

The data submitted must be scientifically sound in order to ensure that the process can reliably produce the required reductions under all the different types of conditions that the process may operate. For example, for processes that may be affected by daily and seasonal variations in the weather, four or more sets of samples taken at different times of the year and during different precipitation conditions (including worst-case conditions) will be needed to make this demonstration.

For national equivalency recommendations, the demonstration must show that the process can reliably produce the desired reductions under the variety of climatic and other conditions that may be encountered at different locations in the United States.

11.4 Guidance on Demonstrating Equivalency for PEC Recommendations

Many of the applicants seeking equivalency do not receive a recommendation from the PEC. The most common reason for this is incomplete applications or insufficient microbiological data. The review process can be both lengthy and expensive, but it can be expedited and simplified if the applicant is aware of the type of data that will be required for the review and submits a complete plan for demonstrating equivalency in a timely fashion.

As described below, equivalency can be demonstrated in one of two ways:

- By comparing operating conditions to existing PFRPs or PSRPs.
- By providing performance and microbiological data.

Comparison to Operating Conditions for Existing PSRPs or PFRPs

If a process is similar to a PSRP or PFRP described in the Part 503 regulation (see Tables 4-2 and 5-1), it may be possible to demonstrate equivalency by providing performance data showing that the process consistently meets or exceeds the conditions specified in the regulation. For example, a process that consistently produces a pH of 12 after 2 hours of contact (the PSRP condition required in Part 503 for lime stabilization) but uses a substance other than lime to raise pH could possibly qualify as a PSRP equivalent. In such cases, microbiological data may not be necessary to demonstrate equivalency.

Process-Specific Performance Data and Microbiologic Data

In all other cases, both performance data and microbiological data (listed below) are needed to demonstrate process equivalency:

- A description of the various parameters (e.g., sewage sludge characteristics, process operating parameters, climatic factors) that influence the microbiological char-

acteristics of the treated sewage sludge (see Section 11.5 for more detail on relevant parameters).

- Sampling and analytical data to demonstrate that the process has reduced microbes to the required levels (see Section 11.3 for a description of levels).
- Discussion of the ability of the treatment process to consistently operate within the parameters necessary to achieve the appropriate reductions.

Sampling and Analytical Methods

Sewage sludge should be sampled using accepted, state-of-the-art techniques for sampling and analyzed using the methods required by Part 503 (see Chapter 9). The sampling program should demonstrate the quality of the sewage sludge that will be produced under a range of conditions. Therefore, sampling events should include a sufficient number of samples to adequately represent product quality, and sampling events should be designed to reflect how the operation might be affected by changes in conditions including climatic and sewage sludge quality variability.

Data Quality

The quality of the data provided is an important factor in EPA's equivalency recommendation. The following steps can help ensure data quality:

- Use of accepted, state-of-the-art sampling techniques (see Chapter 9).
- Obtaining samples that are representative of the expected variation in sewage sludge quality.
- Developing and following quality assurance procedures for sampling.
- Using an independent, experienced laboratory to perform the analysis.

Since processes differ widely in their nature, effects, and processing sequences, the experimental plan to demonstrate that the process meets the requirements for PSRP or PFRP equivalency should be tailored to the process. The permitting authority will evaluate the study design, the accuracy of the data, and the adequacy of the results for supporting the conclusions of the study.

Can Pilot-Scale Data Be Submitted?

Operation of the process at a full-scale facility is desirable. However, if a pilot-scale operation truly simulates full-scale operation, testing on this reduced scale is possible. The permitting authority and the PEC should be contacted to discuss this possibility before testing is initiated. In such cases, it is important to indicate that the data were obtained from a pilot-scale operation, and to discuss why and to what extent this simulates full-scale operation. Any data available from existing full-scale operations would be useful.

The conditions of the pilot-scale operation should be at least as severe as those of a full-scale operation. The arrangement of process steps, degree of mixing, nature of the flow, vessel sizing, proportion of chemicals used, etc. are all part of the requirement. Any substantial degree of departure in the process parameters of the full-scale operation that might reduce the severity of the procedure will invalidate any PEC equivalency recommendations and permitting authority equivalency determinations and will require a retest under the new condition.

11.5 Guidance on Application for Equivalency Recommendations

The following outline and instructions are provided as guidance for preparing applications for equivalency recommendations by EPA's Pathogen Equivalency Committee.

Summary Fact Sheet

The application should include a brief fact sheet that summarizes key information about the process. Any important additional facts should also be included.

Introduction

The full name of the treatment works and the treatment process should be provided. The application should indicate whether it is for recommendation of:

- PSRP or PFRP equivalency.
- Site-specific or national equivalency.

Process Description

The type of sewage sludge used in the process should be described, as well as other materials used in the process. Specifications for these materials should be provided as appropriate. Any terms used should be defined.

The process should be broken down into key steps and graphically displayed in a quantified flow diagram of the wastewater and sewage sludge treatment processes. Details of the wastewater treatment process should be provided and the application should precisely define which steps constitute the beginning and end of sewage sludge treatment.[2] The earliest point at which sewage sludge treatment can be defined as beginning is the point at which the sewage sludge is collected from the wastewater treatment process. Sufficient information should be provided for a mass balance calculation (i.e., actual or relative volumetric flows and solids concentration in and out of all streams, additive rates for bulking agents or other additives). A description of process parameters should be provided for each step of the process, giving typical ranges and mean values where appropriate. The specific process parameters that should be discussed will depend on the type of process and should include any of the following that affect pathogen reduction or process reliability:

Sewage Sludge Characteristics

- Total and volatile solids content of sewage sludge before and after treatment

[2] When defining which steps constitute the "treatment process," bear in mind that all steps included as part of a process equivalent to PSRP or PFRP must be continually operating according to the specifications and conditions that are critical to pathogen reduction.

- Proportion and type of additives (diluents) in sewage sludge
- Chemical characteristics (as they affect pathogen survival/destruction, e.g., pH)
- Type(s) of sewage sludge (unstabilized vs. stabilized, primary vs. secondary, etc.)
- Wastewater treatment process performance data (as they affect sewage sludge type, sewage sludge age, etc.)
- Quantity of treated sewage sludge
- Sewage sludge age
- Sewage sludge detention time

Process Characteristics

- Scale of the system (e.g., reactor size, flow rate)
- Sewage sludge feed process (e.g., batch vs. continuous)
- Organic loading rate (e.g., kg volatile solids/cubic meter/day)
- Operating temperature(s) (including maximum, minimum, and mean temperatures)
- Operating pressure(s) if greater than ambient
- Type of chemical additives and their loading rate
- Mixing
- Aerobic vs. anaerobic
- Duration/frequency of aeration
- Dissolved oxygen level maintained
- Residence/detention time
- Depth of sewage sludge
- Mixing procedures
- Duration and type of storage (e.g., aerated vs. nonaerated)

Climate

- Ambient seasonal temperature range
- Precipitation
- Humidity

The application should include a description of how the process parameters are monitored including information on monitoring equipment. Process uniformity and reliability should also be addressed. Actual monitoring data should be provided whenever appropriate.

Description of Treated Sewage Sludge

The type of treated sewage sludge (biosolids) should be described, as well as the sewage sludge monitoring program for pathogens (if there is one). How and when are samples taken? For what parameters are the samples analyzed? What protocols are used for analysis? What are the results? How long has this program been in operation?

Sampling Technique(s)

The PEC will evaluate the representativeness of the samples and the adequacy of the sampling techniques. For a recommendation of national PFRP equivalency, samples of untreated and treated sewage sludge are usually needed (see Sections 11.3, 4.6, and 10.4). The sampling points should correspond to the beginning and end of the treatment process as defined previously under Process Description above. Chapters 9 and 10 provide guidance on sampling. Samples should be representative of the sewage sludge in terms of location of collection within the sewage sludge pile or batch. The samples taken should include samples from treatment under the least favorable operating conditions that are likely to occur (e.g., wintertime). Information should be provided on:

- Where the samples were collected from within the sewage sludge mass. (If samples were taken from a pile, include a schematic of the pile and indicate where the subsamples were taken.)
- Date and time the samples were collected. Discuss how this timing relates to important process parameters (e.g., turning over, beginning of drying).
- Sampling method used.
- How any composite samples were compiled.
- Total solids of each sample.
- Ambient temperature at time of sampling.
- Temperature of sample at time of sampling.
- Sample handling, preservation, packaging, and transportation procedures.
- The amount of time that elapsed between sampling and analysis.

Analytical Methods

Identify the analytical techniques used and the laboratory(ies) performing the analysis.

Analytical Results

The analytical results should be summarized, preferably in tabular form. A discussion of the results and a summary of major conclusions should be provided. Where appropriate, the results should be graphically displayed. Copies of original data should be provided in an appendix.

Quality Assurance

The application should describe how the quality of the analytical data has been ensured. Subjects appropriate to address are: why the samples are representative; the quality assurance program; the qualifications of the in-house or contract laboratory used; and the rationale for selecting the sampling technique.

Rationale for Why Process Should Be Determined Equivalent

Finally, the application should describe why, in the applicant's opinion, the process qualifies for PSRP or PFRP equivalency. For example, it may be appropriate to describe or review particular aspects of the process that contribute to pathogen reduction, and why the process is expected to operate consistently. Complete references should be provided for any data cited. Applications for a recommendation of national equivalency should discuss why the process effectiveness is expected to be independent of the location of operation.

Appendices

A copy of the complete laboratory report(s) for any sampling and analytical data should be attached as an appendix. Any important supporting literature references should also be included as appendices.

11.6 Pathogen Equivalency Committee Recommendations

Tables 11.1 and 11.2 list processes that the PEC has recommended for use nationally as equivalent to PSRP or PFRP, respectively. Space in the tables limits the detail given for each of the processes. As such individuals having an interest in any of the processes are encouraged to contact either the PEC or the applicant for greater detail on how the process must be operated to be PSRP or PFRP, respectively.

Table 11-1. Processes Recommended as Equivalent to PSRP

Applicant	Process	Process Description
N-Viro Energy Systems, Ltd., Toledo, Ohio	Alkaline Addition to achieve *Lime Stabilization*	Use of cement kiln dust and lime kiln dust (instead of lime) to treat sludge by raising the pH. Sufficient lime or kiln dust is added to sludge to produce a pH of 12 for at least 12 hours of contact
Synox Corp., Jacksonville, FL	OxyOzonation	Batch process where sludge is acidified to pH 3.0 by sulfuric acid; exposed to 1 lb. Ozone/1000 gallons of treated sludge under 60 psig pressure for 60 minutes; depressurized; mixed with 100 mg/l of sodium nitrite and held for ≥2 hours; and stored at ≤ pH 3.5. Limitations imposed were for total solids to be ≤ 4%; temperature must be ≥20°C; and total solids must be ≤ 6.2% before nitrite addition.

11.7 Current Issues

The PEC is continuing to develop methodologies and protocols for the monitoring of pathogen and vector attraction reduction. Current issues include:

- Establishment of a vector attraction reduction equivalency process
- Conducting round robin laboratory testing for pathogens in sewage sludge and biosolids

In addition, the PEC continues to recommend interpretations of the Part 503 with regard to the sampling and monitoring requirements set forth in this document.

Item E 000686

Table 11-2. Processes Recommended as Equivalent to PFRP

Applicant	Process	Process Description
CBI Walker, Inc., Aurora, Illinois	ATP™ Two Stage Sludge Stabilization Process	Sludge is introduced intermittently into a vessel, amounting to 5 to 20% of its volume, where it is heated by both external heat exchange and by the bio-oxidation which results from vigorously mixing air with the sludge (pasteurized) and has a nominal residence time of 18 to 24 hours. Time between feedings of unprocessed sludge can range from 1.2 (@ ~ 65°C) to 4.5 (@ > 60°C) hours. Exiting sludge is heat exchanged with incoming unprocessed sludge. Thus the sludge is cooled before it enters a mesophilic digester. Time and temperature in the first vessel are critical and controlled by the equation below for sludges of ≤ 7% solids, times ≥ 30 minutes, and temperatures ≥50°C. Operations of the reaction vessel during the time-temperature period must be either plug flow or batch mode. $D = 50{,}070{,}000 / 10^{0.1400t}$ where D = time required in days; t = temperature in °C
Fuchs Gas und Wassertechnik, Gmbh, Mayen, Germany	Autothermal Thermophilic Aerobic Digestion	ATAD is a two-stage, autothermal aerobic digestion process. The stages are of equal volume. Treated sludge amounting to 1/3 the volume of a stage is removed every 24 hours from the second stage as product. An equal amount then is taken from the first stage and fed to the second stage. Similarly, an equal amount of untreated sludge is then fed to the first stage. In the 24-hour period between feedings, the sludge in both stages is vigorously agitated and contacted with air. Bio-oxidation takes place and the heat produced increases the temperature. Sludge temperature in the reactors averages between 56 and 57°C for ≥ a 16-hour period, while the overall hydraulic residence time is 6 days.
International Process Systems, Inc., Glastonbury, Connecticut	Type of Composting Process	40 CFR 503.32(a)(7) states that when the within-vessel composting method is employed, the sludge is to be maintained at operating conditions of 55°C or greater for three days, for the product to be PFRP. IPS Process' operation is to further be controlled so that the composting mass passes through a zone in the reactor in which the temperature of the compost is at least 55°C throughout the entire zone, and the time of contact in this zone is at least three days.
K-F Environmental Technologies, Inc., Pompton Plains, NJ	Sludge Drying	Sludge is heated to a minimum temperature of 100°C and indirectly dried to below 10% moisture using oil as a heat transfer medium. The final discharge product has exceeded a temperature of 80°C and is granular dry pellet that can be land applied, incinerated or landfilled. In addition the following conditions must be met: *Dewatered sludge cake is dried by direct or indirect contact with hot gases, and moisture content is reduced to 10% or lower. Sludge particles reach temperatures well in excess of 80°C or the* wet *bulb* temperature *of the gas stream in contact with* the *sludge at the point where it leaves the dryer is in excess of 80°C.*
Lyonnaise des Eaux, Le Pecz-Sur-Seine, France	Two-Phase Thermo-Meso Feed Sequencing Anaerobic Digestion*	Sewage sludge is treated in the absence of air in an acidogenic thermophilic reactor and a mesophilic methanogenic reactor connected in series. The mean cell residence time shall be at least 2.1 days (± 0.05 d) in the acidogenic thermophilic reactor followed by 10.5 days (± 0.3 d) in the mesophilic methanogenic reactor. Feeding of each digester shall be intermittent and occurring 4 times per day every 6 hours. The mesophilic methanogenic reactor shall be fed in priority from the acidogenic thermophilic reactor. Between two consecutive feedings temperature inside the acidogenic thermophilic reactor should be between 49°C and 55°C with 55°C maintained during at least 3 hours. Temperature inside the mesophilic methanogenic reactor shall be constant and at least 37°C.
ATW, Inc. Santa Barbara, CA	Alkaline Stabilization	Manchak process uses quicklime to simultaneously stabilize and pasteurize biosolids. Quicklime, or a combination of quicklime and flyash, is mixed with dewatered biosolids at a predetermined rate in a confined space. An instant exothermic reaction is created in the product wherein the pH is raised in excess of 12 after two hours of contact, in addition, the temperature is raised in excess of 70°C for > 30 minutes.

(continued)

Table 11-2. Continued.

Applicant	Process	Process Description
N-Viro Energy Systems, Ltd., Toledo, OH	Advanced Alkaline stabilization with subsequent accelerated drying	**Alternative 1:** Fine alkaline materials (cement kiln dust, lime kiln dust, quicklime fines, pulverized lime, or hydrated lime) are uniformly mixed by mechanical or aeration mixing into liquid or dewatered sludge to raise the pH to >12 for 7 days. If the resulting sludge is liquid, it is dewatered. The stabilized sludge cake is then air dried (while pH remains >12 for ≥ 7 days) for >30 days and until the cake is ≥ 65% solids. A solids concentration of ≥ 60% is achieved before the pH drops below 12. The mean temperature of the air surrounding the pile is > 5°C (41°F) for the first 7 days. **Alternative 2:** Fine alkaline materials (cement kiln dust, lime kiln dust, quicklime fines, pulverized lime, or hydrated lime) are uniformly mixed by mechanical or aeration mixing into liquid or dewater sludge to raise the pH to > 12 for ≥ 72 hours. If the resulting sludge is liquid, it is dewatered. The sludge cake is then heated, while the pH > 12, using exothermic reactions or other thermal processes to achieve temperatures of ≥ 52°C (126°F) throughout the sludge for ≥ 12 hours. The stabilized sludge is then air dried (while pH > 12 for ≥ 3 days) to ≥ 50% solids.
Synox Corp., Jacksonville, FL	OxyOzonation	Operation occurs in a batch mode and under the following conditions: sludge temperature of > 20°C; sludge solids of < 6% TSS; pH during ozonation of 2.5 - 3.1 and during nitrite contact of 2.6 - 3.5; sludge ORP after ozonation of > 100 mV; nitrite dose of ≥ 670 mg (NO_2)/1 sludge or 16 g (NO_2)/kg sludge solids, whichever is greater is to be mixed into the ozonated sludge. Ozonation takes place in a pressure vessel operating at 60 psig.
Ultraclear, Marlboro, NJ	Microbiological Conditioning and Drying Process (MVCD)	In this process, sludge cake passes through several aerobic-biological type stages (Composting is an example) where different temperatures are maintained for varying times. Stage 1 occurs at 35°C for 7-9 hours; stage 2 occurs at 35-45°C for 8-10 hours; stage 3 occurs at 45-65°C for 7-10 hours; and the last stage is pasteurization at 70-80°C for 7-10 hours. In addition one of two conditions described below must be met: **Condition 1:** *Dewatered sludge cake is dried by direct or indirect contact with hot gases, and moisture content is reduced to 10% or lower. Sludge particles reach temperatures we// in excess of 80°C or the wet bulb temperature of the gas stream in contact with the sludge at the point where it leaves the dryer is in excess of 80°C. OR* **Condition** *2:* A) *Using the within-vessel, static aerated pile, or windrow composting methods, the sludge is maintained at minimum operating conditions of 40°C for 5 days. For 4 hours during the period the temperature exceeds 55°C; {Note: another PSRP-type process should be substituted for that* of *composting};* and B) *Sludge is maintained for at least 30 minutes at a minimum temperature of 70°C.*

*Currently a site specific recommendation. Undergoing further study for national equivalency.

Appendix A
EPA Regional and State Biosolids Coordinators and Listing of EPA Pathogen Equivalency Committee Members

Regional Biosolids Coordinators

Thelma Hamilton Murphy
U.S. EPA Region I
Office of Ecco-System Protection
Boston, MA 02203
(617) 918-1615 (phone)
(617) 918-1505 (fax)
MURPHY.THELMA@EPAMAIL.EPA.GOV

Alia Roufaeal
U.S. EPA Region II
Div. of Enforcement and Compliance Assist.
290 Broadway - 20th Floor
New York, NY 10007-1866
(212) 637-3864
(212) 637-3953
ROUFAEAL.ALIA@EPAMAIL.EPA.GOV

Ann Carkhuff
U.S. EPA Region III
Water Protection Div.
841 Chestnut Street
Philadelphia, PA 19107
(215) 566 5735 (phone)
(215) 566 2301 (fax)
CARKHUFF.ANN@EPAMAIL.EPA.GOV

Madolyn S. Dominy
Region 4 Biosolids Coordinator
U.S. Environmental Protection Agency
61 Forsyth Street, SW
Atlanta, GA 30303
ph. (404)562-9305
fax (404)562-8692
dominy.madolyn@epa.gov

John Colletti
U.S. EPA Region V (WN-16J)
Water Division
77 West Jackson Blvd.
Chicago, IL 60604-3590
(312) 886-6106 (phone)
(312) 886-7804 (fax)
COLLETTI.JOHN@EPAMAIL.EPA.GOV

Stephanie Kordzi (6WQ-PO)
U.S. EPA Region VI
Water Quality Management Division
1445 Ross Avenue #1200
Dallas, TX 75202-2733
(214) 665-7520 (phone)
(214) 665-2191 (phone)
KORDZI.STEPHANIE@EPA.GOV

John Dunn
U.S. EPA Region VII
Waste Management Division
726 Minnesota Ave.
Kansas City, KS 66101
(913) 551-7594 (phone)
(913) 551-7765 (fax)
DUNN.JOHN@EPAMAIL.EPA.GOV

Bob Brobst
Biosolids Program manager (P2-W-P)
U.S. EPA Region VIII
999 18th Street, Suite 500
Denver, CO 80202-2466
(303) 312-6129 (phone)
(303) 312-7084 (fax)
BROBST.BOB@EPA.GOV

Lauren Fondahl
U.S. EPA Region IX (WTR-7)
Biosolids Coordinator
Office of Clean Water Act Compliance
75 Hawthorne Street
San Francisco, CA 94105-3901
(415) 744-1909 (phone)
(415) 744-1235 (fax)
FONDAHL.LAUREN@EPAMAIL.EPA.GOV

Dick Hetherington
U.S. EPA Region X
NPDES Permits Unit (OW-130)
1200 Sixth Avenue
Seattle, WA 98101
(206) 553-1941(phone)
(206) 553-1280 (fax)
HETHERINGTON.DICK@EPAMAIL.EPA.GOV

State Sludge Coordinators

Region I

Connecticut
Bob Norwood/Warren Herzig
CT DEP
Water Compliance Unit
79 Elm Street
Hartford, CT 06106-1632
(860) 424-3746 (phone)

Appendix B
Subpart D of the Part 503 Regulation

[Code of Federal Regulations]
[Title 40, Volume 21, Parts 425 to 699]
[Revised as of July 1, 1998]
From the U.S. Government Printing Office via GPO Access
[CITE: 40CFR503.30]

TITLE 40 - PROTECTION OF ENVIRONMENT

CHAPTER I - ENVIRONMENTAL PROTECTION AGENCY (Continued)

PART 503 - STANDARDS FOR THE USE OR DISPOSAL OF SEWAGE SLUDGE-Table of Contents

Subpart D-Pathogens and Vector Attraction Reduction

Sec. 503.30 Scope.

(a) This subpart contains the requirements for a sewage sludge to be classified either Class A or Class B with respect to pathogens.

(b) This subpart contains the site restrictions for land on which a Class B sewage sludge is applied.

(c) This subpart contains the pathogen requirements for domestic septage applied to agricultural land, forest, or a reclamation site.

(d) This subpart contains alternative vector attraction reduction requirements for sewage sludge that is applied to the land or placed on a surface disposal site.

Sec. 503.31 Special definitions.

(a) Aerobic digestion is the biochemical decomposition of organic matter in sewage sludge into carbon dioxide and water by microorganisms in the presence of air.

(b) Anaerobic digestion is the biochemical decomposition of organic matter in sewage sludge into methane gas and carbon dioxide by microorganisms in the absence of air.

(c) Density of microorganisms is the number of microorganisms per unit mass of total solids (dry weight) in the sewage sludge.

(d) Land with a high potential for public exposure is land that the public uses frequently. This includes, but is not limited to, a public contact site and a reclamation site located in a populated area (e.g., a construction site located in a city).

(e) Land with a low potential for public exposure is land that the public uses infrequently. This includes, but is not limited to, agricultural land, forest, and a reclamation site located in an unpopulated area (e.g., a strip mine located in a rural area).

(f) Pathogenic organisms are disease-causing organisms. These include, but are not limited to, certain bacteria, protozoa, viruses, and viable helminth ova.

(g) pH means the logarithm of the reciprocal of the hydrogen ion concentration.

(h) Specific oxygen uptake rate (SOUR) is the mass of oxygen consumed per unit time per unit mass of total solids (dry weight basis) in the sewage sludge.

(i) Total solids are the materials in sewage sludge that remain as residue when the sewage sludge is dried at 103 to 105 degrees Celsius.

(j) Unstabilized solids are organic materials in sewage sludge that have not been treated in either an aerobic or anaerobic treatment process.

(k) Vector attraction is the characteristic of sewage sludge that attracts rodents, flies, mosquitos, or other organisms capable of transporting infectious agents.

(l) Volatile solids is the amount of the total solids in sewage sludge lost when the sewage sludge is combusted at 550 degrees Celsius in the presence of excess air.

Sec. 503.32 Pathogens.

(a) Sewage sludge-Class A. (1) The requirement in Sec. 503.32(a)(2) and the requirements in either Sec. 503.32(a)(3), (a)(4), (a)(5), (a)(6) (a)(7) or (a)(8) shall be met for a sewage sludge to be classified Class A with respect to pathogens.

(2) The Class A pathogen requirements in Sec. 503.32 (a)(3) through (a)(8) shall be met either prior to meeting or at the same time the vector attraction reduction requirements in Sec. 503.33, except the vector attraction reduction requirements in Sec. 503.33 (b)(6) through (b)(8), are met.

(3) Class A-Alternative 1. (i) Either the density of fecal coliform in the sewage sludge shall be less than 1000 Most Probable Number per gram of total solids (dry weight basis), or the density of *Salmonella* sp. bacteria in the sewage sludge shall be less than three Most Probable Number per four grams of total solids (dry weight basis) at the time the sewage sludge is used or disposed; at the time the sewage sludge is prepared for sale or give away in a bag or other container for application to the land; or at the time the sewage sludge or material derived from sewage sludge is prepared to meet the requirements in Sec. 503.10 (b), (c), (e), or (f).

(ii) The temperature of the sewage sludge that is used or disposed shall be maintained at a specific value for a period of time.

(A) When the percent solids of the sewage sludge is seven percent or higher, the temperature of the sewage sludge shall be 50 degrees Celsius or higher; the time period shall be 20 minutes or longer; and the temperature and time period shall be determined using equation (2), except when small particles of sewage sludge are heated by either warmed gases or an immiscible liquid.

$$D = \frac{131{,}700{,}000}{10^{0.1400t}} \qquad \text{Eq. (2)}$$

Where,
D=time in days.
t=temperature in degrees Celsius.

(B) When the percent solids of the sewage sludge is seven percent or higher and small particles of sewage sludge are heated by either warmed gases or an immiscible liquid, the temperature of the sewage sludge shall be 50 degrees Celsius or higher; the time period shall be 15 seconds or longer; and the temperature and time period shall be determined using equation (2).

(C) When the percent solids of the sewage sludge is less than seven percent and the time period is at least 15 seconds, but less than 30 minutes, the temperature and time period shall be determined using equation (2).

(D) When the percent solids of the sewage sludge is less than seven percent; the temperature of the sewage sludge is 50 degrees Celsius or higher; and the time period is 30 minutes or longer, the temperature and time period shall be determined using equation (3).

$$D = \frac{50{,}070{,}000}{10^{0.1400t}} \qquad \text{Eq.3}$$

Where,
D=time in days.
t=temperature in degrees Celsius.

(4) Class A - Alternative 2. (i) Either the density of fecal coliform in the sewage sludge shall be less than 1000 Most Probable Number per gram of total solids (dry weight basis), or the density of *Salmonella* sp. bacteria in the sewage sludge shall be less than three Most Probable Number per four grams of total solids (dry weight basis) at the time the sewage sludge is used or disposed; at the time the sewage sludge is prepared for sale or give away in a bag or other container for application to the land; or at the time the sewage sludge or material derived from sewage sludge is prepared to meet the requirements in Sec. 503.10 (b), (c), (e), or (f).

(ii)(A) The pH of the sewage sludge that is used or disposed shall be raised to above 12 and shall remain above 12 for 72 hours.

(B) The temperature of the sewage sludge shall be above 52 degrees Celsius for 12 hours or longer during the period that the pH of the sewage sludge is above 12.

(C) At the end of the 72 hour period during which the pH of the sewage sludge is above 12, the sewage sludge shall be air dried to achieve a percent solids in the sewage sludge greater than 50 percent.

(5) Class A - Alternative 3. (i) Either the density of fecal coliform in the sewage sludge shall be less than 1000 Most Probable Number per gram of total solids (dry weight basis), or the density of *Salmonella* sp. bacteria in sewage sludge shall be less than three Most Probable Number per four grams of total solids (dry weight basis) at the time the sewage sludge is used or disposed; at the time the sewage sludge is prepared for sale or give away in a bag or other container for application to the land; or at the time the sewage sludge or material derived from sewage sludge is prepared to meet the requirements in Sec. 503.10 (b), (c), (e), or (f).

(ii)(A) The sewage sludge shall be analyzed prior to pathogen treatment to determine whether the sewage sludge contains enteric viruses.

(B) When the density of enteric viruses in the sewage sludge prior to pathogen treatment is less than one Plaque-forming Unit per four grams of total solids (dry weight basis), the sewage sludge is Class A with respect to enteric viruses until the next monitoring episode for the sewage sludge.

(C) When the density of enteric viruses in the sewage sludge prior to pathogen treatment is equal to or greater

than one Plaque-forming Unit per four grams of total solids (dry weight basis), the sewage sludge is Class A with respect to enteric viruses when the density of enteric viruses in the sewage sludge after pathogen treatment is less than one Plaque-forming Unit per four grams of total solids (dry weight basis) and when the values or ranges of values for the operating parameters for the pathogen treatment process that produces the sewage sludge that meets the enteric virus density requirement are documented.

(D) After the enteric virus reduction in paragraph (a)(5)(ii)(C) of this section is demonstrated for the pathogen treatment process, the sewage sludge continues to be Class A with respect to enteric viruses when the values for the pathogen treatment process operating parameters are consistent with the values or ranges of values documented in paragraph (a)(5)(ii)(C) of this section.

(iii)(A) The sewage sludge shall be analyzed prior to pathogen treatment to determine whether the sewage sludge contains viable helminth ova.

(B) When the density of viable helminth ova in the sewage sludge prior to pathogen treatment is less than one per four grams of total solids (dry weight basis), the sewage sludge is Class A with respect to viable helminth ova until the next monitoring episode for the sewage sludge.

(C) When the density of viable helminth ova in the sewage sludge prior to pathogen treatment is equal to or greater than one per four grams of total solids (dry weight basis), the sewage sludge is Class A with respect to viable helminth ova when the density of viable helminth ova in the sewage sludge after pathogen treatment is less than one per four grams of total solids (dry weight basis) and when the values or ranges of values for the operating parameters for the pathogen treatment process that produces the sewage sludge that meets the viable helminth ova density requirement are documented.

(D) After the viable helminth ova reduction in paragraph (a)(5)(iii)(C) of this section is demonstrated for the pathogen treatment process, the sewage sludge continues to be Class A with respect to viable helminth ova when the values for the pathogen treatment process operating parameters are consistent with the values or ranges of values documented in paragraph (a)(5)(iii)(C) of this section.

(6) Class A - Alternative 4. (i) Either the density of fecal coliform in the sewage sludge shall be less than 1000 Most Probable Number per gram of total solids (dry weight basis), or the density of *Salmonella* sp. bacteria in the sewage sludge shall be less than three Most Probable Number per four grams of total solids (dry weight basis) at the time the sewage sludge is used or disposed; at the time the sewage sludge is prepared for sale or give away in a bag or other container for application to the land; or at the time the sewage sludge or material derived from sewage sludge is prepared to meet the requirements in Sec. 503.10 (b), (c), (e), or (f).

(ii) The density of enteric viruses in the sewage sludge shall be less than one Plaque-forming Unit per four grams of total solids (dry weight basis) at the time the sewage sludge is used or disposed; at the time the sewage sludge is prepared for sale or give away in a bag or other container for application to the land; or at the time the sewage sludge or material derived from sewage sludge is prepared to meet the requirements in Sec. 503.10 (b), (c), (e), or (f), unless otherwise specified by the permitting authority.

(iii) The density of viable helminth ova in the sewage sludge shall be less than one per four grams of total solids (dry weight basis) at the time the sewage sludge is used or disposed; at the time the sewage sludge is prepared for sale or give away in a bag or other container for application to the land; or at the time the sewage sludge or material derived from sewage sludge is prepared to meet the requirements in Sec. 503.10 (b), (c), (e), or (f), unless otherwise specified by the permitting authority.

(7) Class A - Alternative 5. (i) Either the density of fecal coliform in the sewage sludge shall be less than 1000 Most Probable Number per gram of total solids (dry weight basis), or the density of *Salmonella* sp. bacteria in the sewage sludge shall be less than three Most Probable Number per four grams of total solids (dry weight basis) at the time the sewage sludge is used or disposed; at the time the sewage sludge is prepared for sale or given away in a bag or other container for application to the land; or at the time the sewage sludge or material derived from sewage sludge is prepared to meet the requirements in Sec. 503.10 (b), (c), (e), or (f).

(ii) Sewage sludge that is used or disposed shall be treated in one of the Processes to Further Reduce Pathogens described in Appendix B of this part.

(8) Class A - Alternative 6. (i) Either the density of fecal coliform in the sewage sludge shall be less than 1000 Most Probable Number per gram of total solids (dry weight basis), or the density of *Salmonella*, sp. bacteria in the sewage sludge shall be less than three Most Probable Number per four grams of total solids (dry weight basis) at the time the sewage sludge is used or disposed; at the time the sewage sludge is prepared for sale or given away in a bag or other container for application to the land; or at the time the sewage sludge or material derived from sewage sludge is prepared to meet the requirements in Sec. 503.10 (b), (c), (e), or (f).

(ii) Sewage sludge that is used or disposed shall be treated in a process that is equivalent to a Process to Further Reduce Pathogens, as determined by the permitting authority.

(b) Sewage sludge-Class B. (1)(i) The requirements in either Sec. 503.32(b)(2), (b)(3), or (b)(4) shall be met for a sewage sludge to be classified Class B with respect to pathogens.

(ii) The site restrictions in Sec. 503.32(b)(5) shall be met when sewage sludge that meets the Class B pathogen requirements in Sec. 503.32(b)(2), (b)(3), or (b)(4) is applied to the land.

(2) Class B - Alternative 1. (i) Seven samples of the sewage sludge shall be collected at the time the sewage sludge is used or disposed.

(ii) The geometric mean of the density of fecal coliform in the samples collected in paragraph (b)(2)(i) of this section shall be less than either 2,000,000 Most Probable Number per gram of total solids (dry weight basis) or 2,000,000 Colony Forming Units per gram of total solids (dry weight basis).

(3) Class B - Alternative 2. Sewage sludge that is used or disposed shall be treated in one of the Processes to Significantly Reduce Pathogens described in Appendix B of this part.

(4) Class B - Alternative 3. Sewage sludge that is used or disposed shall be treated in a process that is equivalent to a Process to Significantly Reduce Pathogens, as determined by the permitting authority.

(5) Site restrictions. (i) Food crops with harvested parts that touch the sewage sludge/soil mixture and are totally above the land surface shall not be harvested for 14 months after application of sewage sludge.

(ii) Food crops with harvested parts below the surface of the land shall not be harvested for 20 months after application of sewage sludge when the sewage sludge remains on the land surface for four months or longer prior to incorporation into the soil.

(iii) Food crops with harvested parts below the surface of the land shall not be harvested for 38 months after application of sewage sludge when the sewage sludge remains on the land surface for less than four months prior to incorporation into the soil.

(iv) Food crops, feed crops, and fiber crops shall not be harvested for 30 days after application of sewage sludge.

(v) Animals shall not be allowed to graze on the land for 30 days after application of sewage sludge.

(vi) Turf grown on land where sewage sludge is applied shall not be harvested for one year after application of the sewage sludge when the harvested turf is placed on either land with a high potential for public exposure or a lawn, unless otherwise specified by the permitting authority.

(vii) Public access to land with a high potential for public exposure shall be restricted for one year after application of sewage sludge.

(viii) Public access to land with a low potential for public exposure shall be restricted for 30 days after application of sewage sludge.

(c) Domestic septage. (1) The site restrictions in Sec. 503.32 (b)(5) shall be met when domestic septage is applied to agricultural land, forest, or a reclamation site; or (2) The pH of domestic septage applied to agricultural land, forest, or a reclamation site shall be raised to 12 or higher by alkali addition and, without the addition of more alkali, shall remain at 12 or higher for 30 minutes and the site restrictions in Sec. 503.32 (b)(5)(i) through (b)(5)(iv) shall be met.

Sec. 503.33 Vector attraction reduction.

(a)(1) One of the vector attraction reduction requirements in Sec. 503.33 (b)(1) through (b)(10) shall be met when bulk sewage sludge is applied to agricultural land, forest, a public contact site, or a reclamation site.

(2) One of the vector attraction reduction requirements in Sec. 503.33 (b)(1) through (b)(8) shall be met when bulk sewage sludge is applied to a lawn or a home garden.

(3) One of the vector attraction reduction requirements in Sec. 503.33 (b)(1) through (b)(8) shall be met when sewage sludge is sold or given away in a bag or other container for application to the land.

(4) One of the vector attraction reduction requirements in Sec. 503.33 (b)(1) through (b)(11) shall be met when sewage sludge (other than domestic septage) is placed on an active sewage sludge unit.

(5) One of the vector attraction reduction requirements in Sec. 503.33 (b)(9), (b)(10), or (b)(12) shall be met when domestic septage is applied to agricultural land, forest, or a reclamation site and one of the vector attraction reduction requirements in Sec. 503.33 (b)(9) through (b)(12) shall be met when domestic septage is placed on an active sewage sludge unit.

(b)(1) The mass of volatile solids in the sewage sludge shall be reduced by a minimum of 38 percent (see calculation procedures in "Environmental Regulations and Technology - Control of Pathogens and Vector Attraction in Sewage Sludge," EPA/625/R-92/013,1992, U.S. Environmental Protection Agency, Cincinnati, Ohio 45268).

(2) When the 38 percent volatile solids reduction requirement in Sec. 503.33 (b)(1) cannot be met for an anaerobically digested sewage sludge, vector attraction reduction can be demonstrated by digesting a portion of the previously digested sewage sludge anaerobically in the laboratory in a bench-scale unit for 40 additional days at a temperature between 30 and 37 degrees Celsius. When at the end of the 40 days, the volatile solids in the sewage sludge at the beginning of that period is reduced by less than 17 percent, vector attraction reduction is achieved.

(3) When the 38 percent volatile solids reduction requirement in Sec. 503.33 (b)(1) cannot be met for an aerobically digested sewage sludge, vector attraction reduction can be demonstrated by digesting a portion of the previously digested sewage sludge that has a percent solids of two percent or less aerobically in the laboratory in a bench-scale unit for 30 additional days at 20 degrees Celsius. When at the end of the 30 days, the volatile solids in the sewage sludge at the beginning of that period is reduced

by less than 15 percent, vector attraction reduction is achieved.

(4) The specific oxygen uptake rate (SOUR) for sewage sludge treated in an aerobic process shall be equal to or less than 1.5 milligrams of oxygen per hour per gram of total solids (dry weight basis) at a temperature of 20 degrees Celsius.

(5) Sewage sludge shall be treated in an aerobic process for 14 days or longer. During that time, the temperature of the sewage sludge shall be higher than 40 degrees Celsius and the average temperature of the sewage sludge shall be higher than 45 degrees Celsius.

(6) The pH of sewage sludge shall be raised to 12 or higher by alkali addition and, without the addition of more alkali, shall remain at 12 or higher for two hours and then at 11.5 or higher for an additional 22 hours.

(7) The percent solids of sewage sludge that does not contain unstabilized solids generated in a primary wastewater treatment process shall be equal to or greater than 75 percent based on the moisture content and total solids prior to mixing with other materials.

(8) The percent solids of sewage sludge that contains unstabilized solids generated in a primary wastewater treatment process shall be equal to or greater than 90 percent based on the moisture content and total solids prior to mixing with other materials.

(9)(i) Sewage sludge shall be injected below the surface of the land.

(ii) No significant amount of the sewage sludge shall be present on the land surface within one hour after the sewage sludge is injected.

(iii) When the sewage sludge that is injected below the surface of the land is Class A with respect to pathogens, the sewage sludge shall be injected below the land surface within eight hours after being discharged from the pathogen treatment process.

(10)(i) Sewage sludge applied to the land surface or placed on a surface disposal site shall be incorporated into the soil within six hours after application to or placement on the land.

(ii) When sewage sludge that is incorporated into the soil is Class A with respect to pathogens, the sewage sludge shall be applied to or placed on the land within eight hours after being discharged from the pathogen treatment process.

(11) Sewage sludge placed on an active sewage sludge unit shall be covered with soil or other material at the end of each operating day.

(12) The pH of domestic septage shall be raised to 12 or higher by alkali addition and, without the addition of more alkali, shall remain at 12 or higher for 30 minutes.

Appendix C
Determination of Volatile Solids Reduction by Digestion

Introduction

Under 40 CFR Part 503, the ability of sewage sludge to attract vectors must be reduced when sewage sludge is applied to the land or placed on a surface disposal site. One way to reduce vector attraction is to reduce the volatile solids in the sewage sludge by 38% or more (see Section 8.2 of this document). Typically, volatile solids reduction is accomplished by anaerobic or aerobic digestion. Volatile solids reduction also occurs under other circumstances, such as when sewage sludge is stored in an anaerobic lagoon or is dried on sand beds. To give credit for this extra loss in volatile solids, the regulation allows the untreated sewage sludge to be compared with the treated sewage sludge that leaves the treatment works, which should account for all of the volatile solids reduction that could possibly occur. For most processing sequences, the processing steps downstream from the digester, such as short-term storage or dewatering, have no influence on volatile solids content. Consequently, the appropriate comparison is between the sewage sludge entering the digester and the sewage sludge leaving the digester. The remainder of the discussion is limited to this circumstance, except for the final section of this appendix, which compares incoming sewage sludge with the sewage sludge leaving the treatment works.

The Part 503 regulation does not specify a method for calculating volatile solids reduction. Fischer (1984) observed that the United Kingdom has a similar requirement for volatile solids reduction for digestion (40%), but also failed to prescribe a method for calculating volatile solids reduction. Fischer has provided a comprehensive discussion of the ways that volatile solids reduction may be calculated and their limitations. He presents the following equations for determining volatile solids reduction:

- Full mass balance equation
- Approximate mass balance equation
- "Constant ash" equation
- Van Kleeck equation

The full mass balance equation is the least restricted approach but requires more information than is currently collected at a wastewater treatment plant. The approximate mass balance equation assumes steady state conditions. The "constant ash" equation requires the assumption of steady state conditions as well as the assumption that the ash input rate equals the ash output rate. The Van Kleeck equation, which is the equation generally suggested in publications originating in the United States (WPCF, 1968), is equivalent to the constant ash equation. Fischer calculates volatile solids reduction using a number of examples of considerable complexity and illustrates that different methods frequently yield different results.

Fischer's paper is extremely thorough and is highly recommended for someone trying to develop a deep understanding of potential complexities in calculating volatile solids reduction. However, it was not written as a guidance document for field staff faced with the need to calculate volatile solids reduction. The nomenclature is precise but so detailed that it makes comprehension difficult. In addition, two important troublesome situations that complicate the calculation of volatile solids reduction - grit deposition in digesters and decantate removal - are not explicitly discussed. Consequently, this presentation has been prepared to present guidance that describes the major pitfalls likely to be encountered in calculating percent volatile solids reduction.

It is important to note that the calculation of volatile solids reduction is only as accurate as the measurement of volatile solids content in the sewage sludge. The principal cause of error is poor sampling. Samples should be representative, covering the entire charging and withdrawal periods. Averages should cover extended periods of time during which changes in process conditions are minimal. For some treatment, it is expected that periodic checks of volatile solids reduction will produce results so erratic that no confidence can be placed in them. In this case, adequacy of stabilization can be verified by the method described under Options 2 and 3 in Chapter 8 --periodically batch digest anaerobically digested sewage sludge for 40 additional days at 30°C (86°F) to 37°C (99°F), or aerobically digested sewage sludge for 30 additional days at 20°C (68°F). If the additional VS reduction is less than 17% for the anaerobically digested sewage sludge or less than 15% for the aerobically digested sewage sludge, the sewage sludge is sufficiently stable (see Sections 8.3 and 8.4).

Equations for FVSR

The equations for fractional volatile solids reduction (FVSR) that will be discussed below are the same as those developed by Fischer (1984), except for omission of his constant ash equation. This equation gives identical results to the Van Kleeck equation so it is not shown. Fischer's nomenclature has been avoided or replaced with simpler terms. The material balance approaches are called methods rather than equations. The material balances are drawn to fit the circumstances. There is no need to formalize the method with a rigid set of equations.

In the derivations and calculations that follow, both VS (total volatile solids content of the sewage sludge or decantate on a dry solids basis) and FVSR are expressed throughout as fractions to avoid the frequent confusion that occurs when these terms are expressed as percentages. "Decantate" is used in place of the more commonly used "supernatant" to avoid the use of "s" in subscripts. Similarly, "bottoms" is used in place of "sludge" to avoid use of "s" in subscripts.

Method Full Mass Balance

The full mass balance method must be used when steady conditions do not prevail over the time period chosen for the calculation. The chosen time period must be substantial, at least twice the nominal residence time in the digester (nominal residence time equals average volume of sludge in the digester divided by the average volumetric flow rate. Note: when there is decantate withdrawal, volume of sewage sludge withdrawn should be used to calculate the average volumetric flow rate). The reason for the long time period is to reduce the influence of short-term fluctuations in sewage sludge flow rates or compositions. If input compositions have been relatively constant for a long period of time, then the time period can be shortened.

An example where the full mass balance method would be needed is where an aerobic digester is operated as follows:

- Started with the digester 1/4 full (time zero)
- Raw sewage sludge is fed to the digester daily until the digester is full
- Supernatant is periodically decanted and raw sewage sludge is charged into the digester until settling will not occur to accommodate daily feeding (hopefully after enough days have passed for adequate digestion)
- Draw down the digester to about 1/4 full (final time), discharging the sewage sludge to sand beds

The full mass balance is written as follows:

Sum of total volatile solids inputs in feed streams during the entire digestion period = sum of volatile solids outputs in withdrawals of decantate and bottoms + loss of volatile solids + accumulation of volatile solids in the digester. (1)

Loss of volatile solids is calculated from Equation 1. FVSR is calculated by Equation 2:

$$FVSR = \frac{\text{loss in volatile solids}}{\text{sum of volatile solids inputs}} \quad (2)$$

The accumulation of volatile solids in the digester is the final volume in the digester after the drawdown times final volatile solids concentration less the initial volume at time zero times the initial volatile solids concentration.

To properly determine FVSR by the full mass balance method requires determination of all feed and withdrawal volumes, initial and final volumes in the digester, and volatile solids concentrations in all streams. In some cases, which will be presented later, simplifications are possible.

Approximate Mass Balance Method

If volumetric inputs and outputs are relatively constant on a daily basis, and there is no substantial accumulation of volatile solids in the digester over the time period of the test, an approximate mass balance (AMB) may be used. The basic relationship is stated simply:

volatile solids input rate = volatile solids output rate + rate of loss of volatile solids. (3)

The FVSR is given by Equation 2.

No Decantate, No Grit Accumulation (Problem 1)

Calculation of FVSR is illustrated for Problem 1 in Table C-1, which represents a simple situation with no decantate removal and no grit accumulation. An approximate mass balance is applied to the digester operated under constant flow conditions. Because no decantate is removed, the volumetric flow rate of sewage sludge leaving the digester equals the flow rate of sewage sludge entering the digester.

Applying Equations 3 and 2,

$$FY_f = BY_b + \text{loss} \quad (4)$$

$$\text{Loss} = 100(50-30) = 2000 \quad (5)$$

$$FVSR = \frac{\text{Loss}}{FY_f} \quad (6)$$

$$FVSR = \frac{2000}{(100)\ (50)} = 0.40 \quad (7)$$

Nomenclature is given in Table C-1. Note that the calculation did not require use of the fixed solids concentrations.

The calculation is so simple that one wonders why it is so seldom used. One possible reason is that the input and output volatile solids concentrations (Y_f and Y_b) typically will show greater coefficients of variation (standard) deviation divided by arithmetic average) than the fractional volatile solids (VS is the fraction of the sewage sludge solids

Table C-1. Quantitative Information for Example Problems [1,2,3]

Parameter	Symbol	Units	Problem Statement Number 1	2	3	4
Nominal Residence Time	θ	d	20	20	20	20
Time period for averages	—	d	60	60	60	60
Feed Sludge						
Volumetric flow rate	F	m^3/d	100	100	100	100
Volatile solids concentration	Y_f	kg/m^3	50	50	50	50
Fixed solids concentration	X_f	kg/m^3	17	17	17	17
Fractional volatile solids	VS_f	kg/kg	0.746	0.746	0.746	0.746
Mass flow rate of solids	M_f	kg/d	6700	6700	6700	6700
Digested Sludge (Bottoms)						
Volumetric flow rate	B	m^3/d	100	100		49.57
Volatile solids concentration	Y_b	kg/m^3	30	41.42	41.42	41.42
Fixed solids concentration	X_b	kg/m^3	17	15	23.50	23.50
Fractional volatile solids	VS_b	kg/kg	0.638	0.667	0.638	0.638
Mass flow rate of solids	M_b	kg/d	4700	4500		
Decantate						
Volumetric flow rate	D	m^3/d	0	0		50.43
Volatile solids concentration	Y_d	kg/m^3	—	—	12.76	12.76
Fixed solids concentration	X_d	kg/m^3	—	—	7.24	7.24
Fractional volatile solids	VS_d	kg/kg	—	—	0.638	0.638
Mass flow rate of solids	M_d	kg/d	—	—		

[1]Conditions are steady state; all daily flows are constant. Volatile solids are not accumulating in the digester, although grit may be settling out in the digester.
[2]Numerical values are given at 3 or 4 significant figures. This is unrealistic considering the expected accuracy in measuring solids concentrations and sludge volumes. The purpose of extra significant figures is to allow more understandable comparisons to be made of the different calculation methods.
[3]All volatile solids concentrations are based on total solids, not merely on suspended solids.

that is volatile-note the difference between VS and Y). If this is the case, the volatile solids reduction calculated by the approximate mass balance method from several sets of Y_f-Y_b data will show larger deviations than if it were calculated by the Van Kleeck equation using VS_f -VS_b data.

Grit deposition can be a serious problem in both aerobic and anaerobic digestion. The biological processes that occur in digestion dissolve or destroy the substances suspending the grit, and it tends to settle. If agitation is inadequate to keep the grit particles in suspension, they will accumulate in the digester. The approximate mass balance can be used to estimate accumulation of fixed solids.

For Problem 1, the balance yields the following:

$$FX_f = BX_b + \text{fixed solids loss} \quad (8)$$

$$(100)(17) = (100)(17) + \text{Fixed Solids Loss} \quad (9)$$

$$\text{Fixed Solids Loss} = 0 \quad (10)$$

The material balance compares fixed solids in output with input. If some fixed solids are missing, this loss term will be a positive number. Because digestion does not consume fixed solids, it is assumed that the fixed solids are accumulating in the digester. As Equation 10 shows, the fixed solids loss equals zero. Note that for this case, where input and output sewage sludge flow rates are equal, the fixed solids concentrations are equal when there is no grit accumulation.

Grit Deposition (Problem 2)

The calculation of fixed solids is repeated for Problem 2. Conditions in Problem 2 have been selected to show grit accumulation. Parameters are the same as in Problem 1 except for the fixed solids concentration (X_b) and parameters related to it. Fixed solids concentration in the sewage sludge is lower than in Problem 1. Consequently, VS is higher and the mass flow rate of solids leaving is lower than in Problem 1. A mass balance on fixed solids (input rate = output rate + rate of loss of fixed solids) is presented in Equations 11-13.

$$FX_f = BX_b + \text{Fixed Solids Loss} \quad (11)$$

$$\text{Fixed Solids Loss} = FX_f - BX_b \quad (12)$$

$$\text{Fixed Solids Loss} = (100)(7) - (100)(15) = 200 \text{ kg/d} \quad (13)$$

The material balance, which only looks at inputs and outputs, informs us that 200 kg/d of fixed solids have not appeared in the outputs as expected. Because fixed solids are not destroyed, it can be concluded that they are accumulating in the bottom of the digester. The calculation of FVSR for Problem 2 is exactly the same as for Problem 1 (see Equations 4 through 7) and yields the same result. The approximate mass balance method gives the

correct answer for the FVSR despite the accumulation of solids in the digester. As will be seen later, this is not the case when the Van Kleeck equation is used.

Decantate Withdrawal, No Grit Accumulation (Problem 3)

In Problem 3, decantate is withdrawn daily. Volatile and fixed solids concentrations are known for all streams but the volumetric flow rates are not known for decantate and bottoms. It is impossible to calculate FVSR without knowing the relative volumes of these streams. However, they are determined easily by taking a total volume balance and a fixed solids balance, provided it can be assumed that loss of fixed solids (i.e., accumulation in the digester) is zero.

Selecting a basis for F of 100 m^3/d

$$\text{Volume balance: } 100 = B + D \tag{14}$$

$$\text{Fixed solids balance: } 100\,X_f + BX_b + DX_d \tag{15}$$

Because the three Xs are known, B and D can be found. Substituting 100-D for B and the values for the Xs from Problem 3 and solving for D and B,

$$(100)(17) = (100 - D)(23.50) + (D)(7.24) \tag{16}$$

$$D = 40.0\ m^3/d,\ B = 60.0\ m^3/d \tag{17}$$

The FVSR can now be calculated by drawing a volatile solids balance:

$$FY_f = BY_b + DY_d + \text{loss} \tag{18}$$

$$FVSR = \frac{\text{loss}}{FY_f} = \frac{FY_f - BY_b - DY_d}{FY_f} \tag{19}$$

$$FVSR = \frac{(100)(50) - (60)(41.42) - (40)(12.76)}{(100)(50)} = 0\,40 \tag{20}$$

Unless information is available on actual volumes of decantate and sewage sludge (bottoms), it is not possible to deterrnine whether grit is accumulating in the digester. If it is accumulating, the calculated FVSR will be in error.

When the calculations shown in Equations 18 through 20 are made, it is assumed that the volatile solids that are missing from the output streams are consumed by biological reactions that convert them to carbon dioxide and methane. Accumulation is assumed to be negligible. Volatile solids are less likely to accumulate than fixed solids, but it can happen. In poorly mixed digesters, the scum layer that collects at the surface is an accumulation of volatile solids. FVSR calculated by Equations 18 through 20 wiIl be overestimated if the volatile solids accumulation rate is substantial.

Decantate Withdrawal and Grit Accumulation (Problem 4)

In Problem 4, there is suspected grit accumulation. The quantity of B and D can no longer be calculated by Equations 14 and 15 because Equation 15 is no longer correct. The values of B and D must be measured. All parameters in Problem 4 are the same as in Problem 3 except that measured values for B and D are introduced into Problem 4. Values of B and D calculated assuming no grit accumulation (Problem 3--see previous discussion), and measured quantities are compared below:

	Calculated	Measured
B	60	49.57
D	40	50.43

The differences in the values of B and D are not large but they make a substantial change in the numerical value of FVSR. The FVSR for Problem 4 is calculated below:

$$FVSR = \frac{(100)(50) - (49.57)(41.42) - (50.43)(12.76)}{(100)(50)} = 0.461 \tag{21}$$

If it had been assumed that there was no grit accumulation, FVSR would equal 0.40 (see Problem 3). It is possible to determine the amount of grit accumulation that has caused this change. A material balance on fixed solids is drawn:

$$FX_f = BX_b + DX_d + \text{Fixed Solids Loss} \tag{22}$$

The fractional fixed solids loss due to grit accumulation is found by rearranging this equation:

$$\frac{\text{Fixed Solids Loss}}{FX_f} = \frac{FX_f - BX_b - Dx_d}{FX_f} \tag{23}$$

Substituting in the parameter values for Problem 4,

$$\frac{\text{Fixed Solids Loss}}{FX_f} = \frac{(100)(17) - (49.57)(23.50) - (50.43)(7.24)}{(100)(17)} = 0.100 \tag{24}$$

If this fixed solids loss of 10 percent had not been accounted for, the calculated FVSR would have been 13% lower than the correct value of 0.461. Note that if grit accumulation occurs and it is ignored, calculated FVSR will be lower than the actual value.

The Van Kleeck Equation

Van Kleeck first presented his equation without derivation in a footnote for a review paper on sewage sludge treatment processing in 1945 (Van Kleeck, 1945). The equation is easily derived from total solids and volatiie solids mass balances around the digestion system. Consider a digester operated under steady state conditions with decantate and bottom sewage sludge removal. A total solids mass balance and a volatile solids mass balance are:

$$M_f = M_b + M_d + (\text{loss of total solids}) \tag{25}$$

$$M_f \cdot VS_f = M_b \cdot VS_b + M_d \cdot VS_d + (\text{loss of volatile solids}) \quad (26)$$

where
M_f, M_b, and M_d are the mass of solids in the feed, bottoms, and decantate streams.

The masses must be mass of solids rather than total mass of liquid and solid because VS is an unusual type of concentration unit-it is "mass of volatile solids per unit mass of total solids."

It is now assumed that fixed solids are not destroyed and there is no grit deposition in the digester. The losses in Equations 25 and 26 then comprise only volatile solids so the losses are equal. It is also assumed that the VS of the decantate and of the bottoms are the same. This means that the bottoms may have a much higher solids content than the decantate but the proportion of volatile solids to fixed solids is the same for both streams. Assuming then that VS_b equals VS_d, and making this substitution in the defining equation for FVSR (Equation 2),

$$FVSR = \frac{\text{Loss of vol. solids}}{M_f \times VS_f} = 1 - \frac{(M_b + M_d)\, VS_b}{M_f \times VS_f} \quad (27)$$

From Equation 25, recalling that we have assumed that loss of total solids equals loss of volatile solids,

$$M_b + M_d + M_f - \text{loss of vol. solids} \quad (28)$$

Substituting for $M_b + M_d$ into Equation 27,

$$FVSR = 1 - \frac{(M_f - \text{loss of vol. solids}) \cdot VS_b}{M_f \cdot VS_f} \quad (29)$$

Simplifying further,

$$1 - (1/VS_f - FVSR) \cdot VS_b \quad (30)$$

Solving for FVSR,

$$FVSR = \frac{VS_f - VS_b}{VS_f - (VS_f \cdot VS_b)} \quad (31)$$

This is the form of the Van Kleek equation found in WPCF Manual of Practice No. 16 (WPCF, 1968). Van Kleeck (1945) presented the equation in the following equivalent form:

$$FVSR = 1 - \frac{VS_b \times (1 - VS_f)}{VS_f \times (1 - VS_b)} \quad (32)$$

The Van Kleeck equation is applied below to Problems 1 through 4 in Table C-1 and compared to the approximate mass balance equation results:

	1	2	3	4
Approximate Mass Balance (AMB)	0.40	0.40	0.40	0.461
Van Kleeck (VK)	0.40	0.318	0.40	0.40

Problem 1: No decantate and no grit accumulation. Both methods give correct answer.

Problem 2: No decantate but grit accumulation. VK is invalid and incorrect.

Problem 3: Decantate but no grit accumulation. AMB method is valid. VK method is valid only if VS_b equals VS_d.

Problem 4: Decantate and grit accumulation. AMB method valid only if B and D are measured. VK method is invalid.

The Van Kleeck equation is seen to have serious shortcomings when applied to certain practical problems. The AMB method can be completely reliable, whereas the Van Kleeck method is useless under some circumstances.

Average Values

The concentrations and VS values used in the equations will all be averages. For the material balance methods, the averages should be weighted averages according to the mass of solids in the stream in question. The example below shows how to average the volatile solids concentration for four consecutive sewage sludge additions

Addition	Volume	Total Solids Concentration	VS
1	12 m^3	72 kg/m3	0.75
2	8 m^3	50 kg/m3	0.82
3	13 m^3	60 kg/m3	0.80
4	10 m^3	55 kg/m3	0.77

(33)

Weighted by Mass

$$VS\ av = \frac{12 \times 72 \times 0.75 + 8 \times 50 \times 0.82 + 13 \times 60 \times 0.80 + 10 \times 55 \times 0.77}{12 \times 72 + 8 \times 50 + 13 \times 60 + 10 \times 55} = 0.795 \quad (34)$$

Weighted by Volume

$$VS\ av = \frac{12 \times 0.75 + 8 \times 0.82 + 13 \times 0.80 + 10 \times 0.77}{12+8+13+10} = 0.783 \quad (35)$$

Arithmetic Average

$$VS\ av = \frac{0.75 + 0.82 + 0.80 + 0.77}{4} = 0.785 \quad (36)$$

In this example the arithmetic average was nearly as close as the volume-weighted average to the mass-weighted average, which is the correct value.

Which Equation to Use?

Full Mass Balance Method

The full mass balance method allows calculation of volatile solids reduction for all approaches to digestion, even

processes in which the final volume in the digester does not equal the initial volume and where daily flows are not steady. A serious drawback to this method is the need for volatile solids concentration and the volumes of all streams added to or withdrawn from the digester, as well as initial and final volumes and concentrations in the digester. This can be a daunting task, particularly for the small treatment works that is most likely to run digesters in other than steady flow modes. For treatment works of this kind, an "equivalent" method that shows that the sewage sludge has undergone the proper volatile solids reduction is likely to be a better approach than trying to demonstrate 38% volatile solids reduction. An aerobic sewage sludge has received treatment equivalent to a 38% volatile solids reduction if the specific oxygen uptake rate is below a specified maximum. Anaerobically digested sewage sludge has received treatment equivalent to a 38% volatile solids reduction if volatile solids reduction after batch digestion of the sewage sludge for 40 days is less than a specified maximum (EPA, 1992).

Approximate Mass Balance Method

The approximate mass balance method assumes that daily flows are steady and reasonably uniform in composition, and that digester volume and composition do not vary substantially from day to day. Results of calculations and an appreciation of underlying assumptions show that the method is accurate for all cases, including withdrawal of decantate and deposition of grit, provided that in addition to composition of all streams the quantities of decantate and bottoms (the digested sewage sludge) are known. If the quantities of decantate and bottoms are not known, the accumulation of grit cannot be determined. If accumulation of grit is substantial and FVSR is calculated assuming it to be negligible, FVSR will be lower than the true value. The result is conservative and could be used to show that minimum volatile solids reductions are being achieved.

Van Kleeck Method

The Van Kleeck equation has underlying assumptions that should be made clear wherever the equation is presented. The equation is never valid when there is grit accumulation because it assumes the fixed solids input equals fixed solids output. Fortunately, it produces a conservative result in this case. Unlike the AMB method it does not provide a convenient way to check for accumulation of grit. It can be used when decantate is withdrawn, provided VS_b equals VS_d. Just how significant the difference between these VS values can be before an appreciable error in FVSR occurs is unknown, although it could be determined by making up a series of problems with increasing differences between the VS values, calculating FVSR using the AMB method and a Van Kleeck equation, and comparing the results.

The shortcomings of the Van Kleeck equation are substantial, but the equation has one strong point: The VS of the various sewage sludge and decantate streams are likely to show much lower coefficients of variation (standard deviation divided by arithmetic average) than volatile solids and fixed solids concentrations. Reviews of data are needed to determine how seriously the variation in concentrations affect the confidence interval of FVSR calculated by both methods. A hybrid approach may turn out to be advantageous. The AMB method could be used first to determine if grit accumulation is occurring. If grit is not accumulating, the Van Kleeck equation could be used. If decantate is withdrawn, the Van Kleeck equation is appropriate, particularly if the decantate is low in total solids. If not, and if VS_d differs substantially from VS_b, it could yield an incorrect answer.

Volatile Solids Loss Across All Sewage Sludge Treatment Processes

For cases when appreciable volatile solids reduction can occur downstream from the digester (for example, as would occur in air drying or lagoon storage), it is appropriate to calculate the volatile solids loss from the point at which the sewage sludge enters the digester to the point at which the sewage sludge leaves the treatment works. Under these circumstances, it is virtually never possible to use the approximate mass balance approach, because flow rates are not uniform. The full mass balance could be used in principle, but practical difficulties such as measuring the mass of the output sewage sludge (total mass, not just mass of solids) that relates to a given mass of entering sewage sludge make this also a practical impossibility. Generally then, the only option is to use the Van Kleeck equation, because only the percent volatile solids content of the entering and exiting sewage sludge is needed to make this calculation. As noted earlier, this equation will be inappropriate if there has been a selective loss of high volatility solids (e.g., bacteria) or low volatility solids (e.g., grit) in any of the sludge processing steps.

To make a good comparison, there should be good correspondence between the incoming sewage sludge and the treated sewage sludge to which it is being compared (see Section 10.4). For example, when sewage sludge is digested for 20 days, then dried on a sand bed for 3 months, and then removed, the treated sludge should be compared with the sludge fed to the digester in the preceding 3 or 4 months. If no selective loss of volatile or nonvolatile solids has occurred, the Van Kleeck equation (see Equation 31) can be used to calculate volatile solids reduction.

Appendix D
Guidance on Three Vector Attraction Reduction Tests

This appendix provides guidance for the vector attraction reduction Options 2,3, and 4 to demonstrate reduced vector attraction (see Chapter 8 for a description of these requirements).

1. Additional Digestion Test for Anaerobically Digested Sewage Sludge

Background

The additional digestion test for anaerobically digested sewage sludge is based on research by Jeris et al. (1985). Farrell and Bhide (1993) explain in more detail the origin of the time and volatile solids reduction requirements of the test.

Jeris et al. (1985) measured changes in many parameters including volatile solids content while carrying out additional digestion of anaerobically digested sludge from several treatment works for long periods. Samples were removed from the digesters weekly for analysis. Because substantial amount of sample was needed for all of these tests, they used continuously mixed digesters of 18 liters capacity. The equipment and procedures of Jeris et al., although not complex, appear to be more elaborate than needed for a control test. EPA staff (Farrell and Bhide, 1993) have experimented with simplified tests and the procedure recommended is based on their work.

Recommended Procedure

The essentials of the test are as follows:

- Remove, from the plant-scale digester, a representative sample of the sewage sludge to be evaluated to determine additional volatile solids destruction. Keep the sample protected from oxygen and maintain it at the temperature of the digester. Commence the test within 6 hours after taking the sample.

- Flush fifteen 100-mL volumetric flasks with nitrogen, and add approximately 50 mL of the sludge to be tested into each flask. Frequently mix the test sludge during this operation to assure that its composition remains uniform. Select five flasks at random, and determine total solids content and volatile solids content, using the entire 50 mL for the determination. Seal each of the remaining flasks with a stopper with a single glass tube through it to allow generated gases to escape.

- Connect the glass tubing from each flask through a flexible connection to a manifold. To allow generated gases to escape and prevent entry of air, connect the manifold to a watersealed bubbler by means of a vertical glass tube. The tube should be at least 30-cm long with enough water in the bubbler so that an increase in atmospheric pressure will not cause backflow of air or water into the manifold. Maintain the flasks containing the sludge at constant temperature either by inserting them in a water bath (the sludge level in the flasks must be below the water level in the bath) or by placing the entire apparatus in a constant temperature room or box. The temperature of the additional digestion test should be the average temperature of the plant digester, which should be in the range of 30°C to 40°C (86°F to 104°F). Temperature should be controlled within + 0.15°C (0.27°F).

- Each flask should be swirled every day to assure adequate mixing, using care not to displace sludge up into the neck of the flask. Observe the water seal for the first few days of operation. There should be evidence that gas is being produced and passing through the bubbler.

- After 20 days, withdraw five flasks at random. Determine total and volatile solids content using the entire sample for the determination. Swirl the flask vigorously before pouring out its contents to minimize the hold up of thickened sludge on the walls and to assure that any material left adhering to the flask walls will have the same average composition as the material withdrawn. Use a consistent procedure. If holdup on walls appears excessive, a minimal amount of distilled water may be used to wash solids off the walls. Total removal is not necessary, but any solids left on the walls should be approximately of the same composition as the material removed.

- After 40 days, remove the remaining five flasks. Determine total and volatile solids content using the entire sample from each flask for the determination. Use the same precautions as in the preceding step to remove virtually all of the sludge, leaving only material with the same approximate composition as the material removed.

Total and volatile solids contents are determined using the procedures of Method 2540 G of Standard Methods (APHA, 1992).

Mean values and standard deviations of the total solids content, the volatile solids content, and the percent volatile solids are calculated. Volatile solids reductions that result from the additional digestion periods of 20 and 40 days are calculated from the mean values by the Van Kleeck equation and by a material balance (refer to Appendix C for a general description of these calculations). The results obtained at 20 days give an early indication that the test is proceeding satisfactorily and will help substantiate the 40-day result.

Alternative approaches are possible. The treatment works may already have versatile bench-scale digesters available. This equipment could be used for the test, provided accuracy and reproducibility can be demonstrated. The approach described above was developed because Farrell and Bhide (1993) in their preliminary work experienced much difficulty in withdrawing representative samples from large digesters even when care was taken to stir the digesters thoroughly before sampling. If an alternative experimental setup is used, it is still advisable to carry out multiple tests for the volatile solids content in order to reduce the standard error of this measurement, because error in the volatile solids content measurement is inflated by the nature of the equation used to calculate the volatile solids reduction.

Variability in flow rates and nature of the sludge will result in variability in performance of the plant-scale digesters. It is advisable to run the additional digestion test routinely so that sufficient data are available to indicate average performance. The arithmetic mean of successive tests (a minimum of three is suggested) should show an additional volatile solids reduction of $\leq$ 17%.

Calculation Details

Appendix C, Determination of Volatile Solids Reduction by Digestion, describes calculation methods to use for digesters that are continuously fed or are fed at least once a day. Although the additional anaerobic digestion test is a batch digestion, the material balance calculations approach is the same. Masses of starting streams (input streams) are set equal to masses of ending streams (output streams).

The test requires that the fixed volatile solids reduction (FVSR) be calculated both by the Van Kleeck equation and the material balance method. The Van Kleeck equation calculations can be made in the manner described in Appendix C.

The calculation of the volatile solids reduction (and the fixed fractional solids reduction [FFSR]) by the mass balance method shown below has been refined by subtracting out the mass of gas lost from the mass of sludge at the end of the digestion step. For continuous digestion, this loss of mass usually is ignored, because the amount is small in relation to the total digesting mass, and mass before and after digestion are assumed to be the same. Considering the inherent difficulty in matching mass and composition entering to mass and composition leaving for a continuous process, this is a reasonable procedure. For batch digestion, the excellent correspondence between starting material and final digested sludge provides much greater accuracy in the mass balance calculation, so inclusion of this lost mass is worthwhile.

In the equations presented below, concentrations of fixed and volatile solids are mass fractions--mass of solids per unit mass of sludge (mass of sludge includes both the solids and the water in the sludge)-- and are indicated by, the symbols lowercase y and x. This is different from the usage in Appendix C where concentrations are given in mass per unit volume, and are indicated by the symbols uppercase y and x. This change has been made because masses can be determined more accurately than volumes in small-scale tests.

In the material balance calculation, it is assumed that as the sludge digests, volatile solids and fixed solids are converted to gases that escape or to volatile compounds that distill off when the sludge is dried. Any production or consumption of water by the biochemical reactions in digestion is assumed to be negligible. The data collected (volatile solids and fixed solids concentrations of feed and digested sludge) allow mass balances to be drawn on volatile solids, fixed solids, and water. As noted, it is assumed that there is no change in water mass -- all water in the feed is present in the digested sludge. Fractional reductions in volatile solids and fixed solids can be calculated from these mass balances for the period of digestion. Details of the calculation of these relationships are given by Farrell and Bhide (1993). The final form of the equations for fractional volatile solids reduction (mass balance [m.b.] method) and fractional fixed solids reduction (m.b. method) are given below:

$$FVSR(m.b.) = \frac{y_f(1-x_b)-y_b(1-x_f)}{y_f(1-x_b-y_b)} \quad (1a)$$

$$FFSR(m.b.) = \frac{x_f(1-y_b)-x_b(1-y_f)}{x_f(1-x_b-y_b)} \quad (1b)$$

where:

y = mass fraction of volatile solids in the liquid sludge
x = mass fraction of fixed solids in the liquid sludge
f = indicates feed sludge at start of the test
b = indicates "bottoms" sludge at end of the test

If the fixed solids loss is zero, these two equations are reduced to Equation 2 below:

$$FVSR(m.b.) = (y_f - y_b)/y_f\,(1-y_b) \quad (2)$$

If the fixed solids loss is not zero but is substantially smaller than the volatile solids reduction, Equation 2 gives surprisingly accurate results. For five sludges batch-digested by Farrell and Bhide (1993), the fixed solids reduc-

tions were about one-third of the volatile solids reductions. When the FVSR(m.b.) calculated by Equation 1a averaged 15%, the FVSR(m.b.) calculated by Equation 2 averaged 14.93%, which is a trivial difference.

The disappearance of fixed solids unfortunately has a relatively large effect on the calculation of FVSR by the Van Kleeck equation. The result is lower than it should be. For five sludges that were batch-digested by Farrell and Bhide (1993), the FVSR calculated by the Van Kleeck method averaged 15%, whereas the FVSR (m.b.) calculated by Equation 1a or 2 averaged about 20%. When the desired endpoint is an FVSR below 17%, this is a substantial discrepancy.

The additional digestion test was developed for use with the Van Kleeck equation, and the 17% requirement is based on results calculated with this equation. In the future, use of the more accurate mass balance equation may be required, with the requirement adjusted upward by an appropriate amount. This cannot be done until more data with different sludge become available.

2. Specific Oxygen Uptake Rate

Background

The specific oxygen uptake rate of a sewage sludge is an accepted method for indicating the biological activity of an activated sewage sludge mixed liquor or an aerobically digesting sludge. The procedure required by the Part 503 regulation for this test is presented in Standard Methods (APHA, 1992) as Method 2710 B, Oxygen-Consumption Rate.

The use of the specific oxygen uptake rate (SOUR) has been recommended by Eikum and Paulsrud (1977) as a reliable method for indicating sludge stability provided temperature effects are taken into consideration. For primary sewage sludges aerobically digested at 18°C (64°F), sludge was adequately stabilized (i.e., it did not putrefy and cause offensive odors) when the SOUR was less than 1.2 mg O_2/hr/g VSS (volatile suspended solids). The authors investigated several alternative methods for indicating stability of aerobically digested sludges and recommended the SOUR test as the one with the most advantages and the least disadvantages.

Ahlberg and Boyko (1972) also recommend the SOUR as an index of stability. They found that, for aerobic digesters operated at temperatures above 10°C (50°F), SOUR fell to about 2.0 mg O_2/hr/g VSS after a total sludge age of 60 days and to 1.0 mg O_2/hr/g VSS after about 120 days sludge age. These authors state that a SOUR of less than 1.0 mg O_2/hr/g VSS at temperatures above 10°C (50°F) indicates a stable sludge.

The results obtained by these authors indicate that long digestion times--more than double the residence time for most aerobic digesters in use today--are needed to eliminate odor generation from aerobically digested sludges. Since the industry is not being deluged with complaints about odor from aerobic digesters, it appears that a higher SOUR standard can be chosen than they suggest without causing problems from odor (and vector attraction).

The results of long-term batch aerobic digestion tests by Jeris et al. (1985) provide information that is helpful in setting a SOUR requirement that is reasonably attainable and still protective. Farrell and Bhide (1993) reviewed the data these authors obtained with four sewage sludges from aerobic treatment processes and concluded that a standard of 1.5 mg O_2/hr/g TS at 20°C (68°F) would discriminate between adequately stabilized and poorly stabilized sludges. The "adequately digested" sludges were not totally trouble-free, i.e., it was possible under adverse conditions to develop odorous conditions. In all cases where the sludge was deemed to be adequate, minor adjustment in plant operating conditions created an acceptable sludge.

The SOUR requirement is based on total solids rather than volatile suspended solids. This usage is preferred for consistency with the rest of the Part 503 regulation where all loadings are expressed on a total solids basis. The use of total solids concentration in the SOUR calculation is rational since the entire sludge solids and not just the volatile solids degrade and may exert some oxygen demand. Making an adjustment for the difference caused by basing the requirement on TS instead of VSS, the standard is about 1.8 times higher than Eikum and Paulsrud's recommended value and 2.1 times higher than Ahlberg and Boykos' recommendation.

Unlike anaerobic digestion, which is typically conducted at 35°C (95°F), aerobic digestion is carried out without any deliberate temperature control. The temperature of the digesting sludge will be close to ambient temperature, which can range from 5°C to 30°C (41°F to 86°F). In this temperature range, SOUR increases with increasing temperature. Consequently, if a requirement for SOUR is selected, there must be some way to convert SOUR test results to a standard temperature. Conceivably, the problem could be avoided if the sludge were simply heated or cooled to the standard temperature before running the SOUR test. Unfortunately, this is not possible, because temperature changes in digested sludge cause short-term instabilities in oxygen uptake rate (Benedict and Carlson [1973], Farrell and Bhide [1993]).

Eikum and Paulsrud (1977) recommend that the following equation be used to adjust the SOUR determined at one temperature to the SOUR for another temperature:

$$(SOUR)_{T1} / (SOUR)_{T2} = \theta^{(T1-T2)} \quad (3)$$

where:

$(SOUR)_{T1}$ = specific oxygen uptake rate at T_1
$(SOUR)_{T2}$ = specific oxygen uptake rate at T_2
θ = the Streeter-Phelps temperature sensitivity coefficient

These authors calculated the temperature sensitivity coefficient using their data on the effect of temperature on the rate of reduction in volatile suspended solids with time during aerobic digestion. This is an approximate approach, because there is no certainty that there is a one-to-one relationship between oxygen uptake rate and rate of volatile solids disappearance. Another problem is that the coeffficient depends on the makeup of each individual sludge. For example, Koers and Mavinic (1977) found the value of θ to be less than 1.072 at temperatures above 15°C (59°F) for aerobic digestion of waste activated sludges, whereas Eikum and Paulsrud (1977) determined θ to equal 1.112 for primary sludges. Grady and Lim (1980) reviewed the data of several investigators and recommended that θ = 1.05 be used for digestion of waste-activated sludges when more specific information is not available. Based on a review of the available information and their own work, Farrell and Bhide (1993) recommend that Eikum and Paulsruds' temperature correction procedure be utilized, using a temperature sensitivity coefficient in the range of 1.05 to 1.07.

Recommended Procedure for Temperature Correction

A SOUR of 1.5 mg O_2/hr/g total solids at 20°C (68°F) was selected to indicate that an aerobically digested sludge has been adequately reduced in vector attraction.

The SOUR of the sludge is to be measured at the temperature at which the aerobic digestion is occurring in the treatment works and corrected to 20°C (68°F) by the following equation:

$$SOUR_{20} = SOUR_T \times \theta^{(20-T)} \quad (4)$$

where
θ = 1.05 above 20°C (68°F)
1.07 below 20°C (68°F)

This correction may be applied only if the temperature of the sludge is between 10°C and 30°C (50°F and 86°F). The restriction to the indicated temperature range is required to limit the possible error in the SOUR caused by selecting an improper temperature coefficient. Farrell and Bhide's (1993) results indicate that the suggested values for θ will give a conservative value for SOUR when translated from the actual temperature to 20°C (68°F).

The experimental equipment and procedures for the SOUR test are those described in Part 2710 B, Oxygen Consumption Rate, of Standard Methods (APHA, 1992). The method allows the use of a probe with an oxygen-sensitive electrode or a respirometer. The method advises that manufacturer's directions be followed if a respirometer is used. No further reference to respirometric methods will be made here. A timing device is needed as well as a 300-mL biological oxygen demand (BOD) bottle. A magnetic mixer with stirring bar is also required.

The procedure of Standard Method 2710 B should be followed with one exception. The total solids concentration instead of the volatile suspended solids concentration is used in the calculation of the SOUR. Total solids concentration is determined by Standard Method 2540 G. Method 2710 B cautions that if the suspended solids content of the sludge is greater than 0.5%, additional stirring besides that provided by the stirring bar be considered. Experiments by Farrell and Bhide (1993) were carried out with sludges up to 2% in solids content without difficulty if the SOUR was lower than about 3.0 mg O_2/g/h. It is possible to verify that rnixing is adequate by running repeat measurements at several stirrer bar speeds. If stirring is adequate, oxygen uptake will be independent of stirrer speed.

The inert mineral solids in the wastewater in which the sludge particles are suspended do not exert an oxygen demand and probably should not be part of the total solids in the SOUR determination. Ordinarily, they are such a small part of the total solids that they can be ignored. If the ratio of inert dissolved mineral solids in the treated wastewater to the total solids in the sludge being tested is greater than 0.15, a correction should be made to the total solids concentration. Inert dissolved mineral solids in the treated wastewater effluent is determined by the method of Part 2540 B of Standard Methods (APHA, 1992). This quantity is subtracted from the total solids of the sludge to determine the total solids to be used in the SOUR calculation.

The collection of the sample and the time between sample collection and measurement of the SOUR are important. The sample should be a composite of grab samples taken within a period of a few minutes duration. The sample should be transported to the laboratory expeditiously and kept under aeration if the SOUR test cannot be run immediately. The sludge should be kept at the temperature of the digester from which it was drawn and aerated thoroughly before it is poured into the BOD bottle for the test. If the temperature differs from 20°C (68°F) by more than ±10°C (±18°F), the temperature correction may be inappropriate and the result should not be used to prove that the sewage sludge meets the SOUR requirement.

Variability in flow rates and nature of the sludge will result in variability in performance of the plant-scale digesters. It is advisable to run the SOUR test routinely so that sufficient data are available to indicate average performance. The arithmetic mean of successive tests-a minimum of seven over 2 or 3 weeks is suggested-should give a SOUR of ≤ 1.5 mg O_2/hr/g total solids.

3. Additional Digestion Test for Aerobically Digested Sewage Sludge

Background

Part 503 lists several options that can be used to demonstrate reduction of vector attraction in sewage sludge. These options include reduction of volatile solids by 38% and demonstration of the SOUR value discussed above (see also Chapter 8). These options are feasible for many, but not all, digested sludges. For example, sludges from extended aeration treatment works that are aerobically di-

gested usually cannot meet this requirement because they already are partially reduced in volatile solids content by their exposure to long aeration times in the wastewater treatment process.

The specific oxygen uptake test can be utilized to evaluate aerobic sludges that do not meet the 38% volatile solids reduction requirement. Unfortunately, this test has a number of limitations. It cannot be applied if the sludges have been digested at temperatures lower than 10°C (50°F) or higher than 30°C (86°F). It has not been evaluated under all possible conditions of use, such as for sludges of more than 2% solids.

A straightforward approach for aerobically treated sludges that cannot meet either of the above criteria is to determine to what extent they can be digested further. If they show very little capacity for further digestion, they will have a low potential for additional biodegradation and odor generation that attracts vectors. Such a test necessarily takes many days to complete, because time must be provided to get measurable biodegradation. Under most circumstances, this is not a serious drawback. If a digester must be evaluated every 4 months to see if the sewage sludge meets vector attraction reduction requirements, it will be necessary to start a regular assessment program. A record can be produced showing compliance. The sludge currently being produced cannot be evaluated quickly but it will be possible to show compliance over a period of time.

The additional digestion test for aerobically digested sludges in Part 503 is based on research by Jeris et al. (1985), and has been discussed by Farrell et al. (EPA, 1992). Farrell and Bhide (1993) explain in more detail the origin of the time and volatile solids reduction requirements of the test.

Jeris et al. (1985) demonstrated that several parameters--volatile solids reduction, COD, BOD, and SOUR--declined smoothly and approached asymptotic values with time as sludge was aerobically digested. Any one of these parameters potentially could be used as an index of vector attraction reduction for aerobic sludges. SOUR has been adopted (see above) for this purpose. Farrell and Bhide (1993) have shown that the additional volatile solids reduction that occurs when sludge is batch digested aerobically for 30 days correlates equally as well as SOUR with the degree of vector attraction reduction of the sludge. They recommend that a sewage sludge be accepted as suitably reduced in vector attraction when it shows less than 15% additional volatile solids reduction after 30 days additional batch digestion at 20°C (68°F). For three out of four sludges investigated by Jeris et al. (1985), the relationship between SOUR and additional volatile solids reduction showed that the SOUR was approximately equal to 1.5 mg O_2/hr/g (the Part 503 requirement for SOUR) when additional volatile solids reduction was 15%. The two requirements thus agree well with one another.

Recommended Procedure

There is considerable flexibility in selecting the size of the digesters used for the additional aerobic digestion test. Farrell and Bhide (1993) used a 20-liter fish tank. A tank of rectangular cross-section is suggested because sidewalls are easily accessible and are easily scraped clean of adhering solids. The tank should have a loose-fitting cover that allows air to escape. It is preferable to vent exhaust gas to a hood to avoid exposure to aerosols. Oil and particle-free air is supplied to the bottom of the digester through porous stones at a rate sufficient to thoroughly mix the sewage sludge. This will supply adequate oxygen to the sludge, but the oxygen level in the digesting sludge should be checked with a dissolved oxygen meter to be sure that the supply of oxygen is adequate. Oxygen level should be at least 2 mg/L. Mechanical mixers also were used to keep down foam and improve mixing.

If the total solids content of the sewage sludge is greater than 2%, the sludge must be diluted to 2% solids with secondary effluent at the start of the test. The requirement stems from the results of Reynolds (1973) and Malina (1966) which demonstrate that rate of volatile solids reduction decreases as the feed solitis concentration increases. Thus, for example, a sludge with a 2% solids content that showed more than 15% volatile solids reduction when digested for 30 days might show a lower volatile solids reduction and would pass the test if it were at 4%. This dilution may cause a temporary change in rate of volatile solids reduction. However, the long duration of the test should provide adequate time for recovery and demonstration of the appropriate reduction in volatile solids content.

When sampling the sludge, care should be taken to keep the sludge aerobic and avoid unnecessary temperature shocks. The sludge is digested at 20°C (68°F) even if the digester was at some other temperature. It is expected that the bacterial population will suffer a temporary shock if there is a substantial temperature change, but the test is of sufficient duration to overcome this effect and show a normal volatile solids reduction. Even if the bacteria are shocked and do not recover completely, the test simulates what would happen to the sludge in the environment. If it passes the test, it is highly unlikely that the sludge will attract vectors when used or disposed to the environment. For example, if a sludge digested at 35°C (95°F) has not been adequately reduced in volatile solids and is shocked into biological inactivity for 30 days when its temperature is lowered to 20°C (68°F), it will be shocked in the same way if it is applied to the soil at ambient temperature. Consequently, it is unlikely to attract vectors.

The digester is charged with about 12 liters of the sewage sludge to be additionally digested, and aeration is commenced. The constant flow of air to the aerobic digestion test unit will cause a substantial loss of water from the digester. Water loss should be made up every day with distilled water.

Solids that adhere to the walls above and below the water line should be scraped off and dispersed back into the sludge daily. The temperature of the digesting sludge should be approximately 20°C (68°F). If the temperature of the labora-

tory is maintained at about 22°C (72°F), evaporation of water from the digester will cool the sludge to about 20°C (68°F).

Sewage sludge is sampled every week for five successive weeks. Before sampling, makeup water is added (this will generally require that air is temporarily shut off to allow the water level to be established), and sludge is scraped off the walls and redistributed into the digester. The sludge in the digester is thoroughly mixed with a paddle before sampling, making sure to mix the bottom sludge with the top. The sample is comprised of several grab samples collected with a ladle while the digester is being mixed. The entire sampling procedure is duplicated to collect a second sample.

Total and volatile solids contents of both samples are determined preferably by Standard Method 2540 G (APHA, 1992). Percent volatile solids is calculated from total and volatile solids content. Standard Methods (APHA, 1992) states that duplicates should agree within 5% of their average. If agreement is substantially poorer than this, the sampling and analysis should be repeated.

Calculation Details

Fraction volatile solids reduction is calculated by the Van Kleeck formula (see Appendix C) and by a mass balance method. The mass balance (m.b.) equations become very simple, because final mass of sludge is made very nearly equal to initial mass of sludge by adjusting the volume by adding water. These equations for fractional volatile solids reduction (FVSR) and fractional fixed solids reduction (FFSR) are:

$$FVSR(m.b.) = (y_f - y_b) / y_f \quad (5a)$$

$$FFSR(m.b.) = (x_f - x_b) / x_f \quad (5b)$$

where:

y and x = mass fraction of volatile and fixed solids, respectively (see previous section on "Calculation details" for explanation of "mass fraction")

f and b = subscripts indicating initial and final sludges

This calculation assumes that initial and final sludge densities are the same. Very little error is introduced by this assumption.

The calculation of the fractional fixed solids reduction is not a requirement of the test, but it will provide useful information.

The test was developed from information based on the reduction in volatile solids content calculated by the Van Kleeck equation. As noted in the section on the additional anaerobic digestion test, for batch processes the material balance procedure for calculating volatile solids reduction is superior to the Van Kleeck approach. It is expected that the volatile solids reduction by the mass balance method will show a higher volatile solids reduction than the calculation made by using the Van Kleeck equation.

Appendix E
Determination of Residence Time for Anaerobic and Aerobic Digestion

Introduction

The PSRP and PFRP specifications in 40 CFR 257 for anaerobic and aerobic digestion not only specify temperatures but also require minimum mean cell residence times of the sludge in the digesters. The mean cell residence time is the time that the sludge particles are retained in the digestion vessel under the conditions of the digestion. The calculation of residence time is ordinarily simple but it can become complicated under certain circumstances. This appendix describes how to make this calculation for most of the commonly encountered modes for operating digesters.

Approach

The discussion has to be divided into two parts: residence time for batch operation and for plug flow, and residence time for fully mixed digesters. For batch operation, residence time is obvious--it is the duration of the reaction. For plug flow, the liquid--solid mixture that is sludge passes through the reactor with no backward or forward mixing. The time it takes the sludge to pass through the reactor is the residence time. It is normally calculated by the following equation:

$$\theta = V/q \quad (1)$$

where
θ = plug flow solids residence time
V = volume of the liquid in the reactor
q = volume of the liquid leaving the reactor

Normally the volume of liquid leaving the reactor will equal the volume entering. Conceivably, volume leaving could be smaller (e.g., because of evaporation losses) and residence time would be longer than expected if θ were based on inlet flow. Ordinarily, either inlet or outlet flow rate can be used.

For a fully mixed reactor, the individual particles of the sludge are retained for different time periods--some particles escape very soon after entry whereas others circulate in the reactor for long periods before escaping. The average time in the reactor is given by the relationship:

$$\theta_n = \frac{\Sigma(\delta s \times \theta)}{\Sigma(\delta s)} \quad (2)$$

where
δs = an increment of sludge solids that leaves the reactor
θ = time period this increment has been in the reactor
θ_n = nominal average solids residence time

When the flow rates of sludge into and out of the completely mixed vessel are constant, it can be demonstrated that this equation reduces to:

$$\theta_n = \frac{VC_v}{qC_q} \quad (3)$$

where
V = reactor volume
q = flow rate leaving
C_v = concentration of solids in the reactor
C_q = concentration of solids in exiting sewage sludge

It is important to appreciate that q is the flow rate leaving the reactor. Some operators periodically shut down reactor agitation, allow a supernatant layer to form, decant the supernatant, and resume operation. Under these conditions, the flow rate entering the reactor is higher than the flow rate of sludge leaving.

Note that in Equation 3, VC_v is the mass of solids in the system and qC is the mass of solids leaving. Ordinarily C_v equals C_q and these terms could be canceled. They are left in the equation because they show the essential form of the residence time equation:

$$\theta_n = \frac{\text{mass of solids in the digester}}{\text{mass flow rate of solids leaving}} \quad (4)$$

Using this form, residence time for the important operating mode in which sludge leaving the digester is thickened and returned to the digester can be calculated.

In many aerobic digestion installations, digested sludge is thickened with part of the total volume returned to increase residence time and part removed as product. The calculation follows Equation 4 and is identical with the SRT (solids retention time) calculation used in activated sludge process calculations. The focus here is on the solids in the digester and the solids that ultimately leave the system. Applying Equation 4 for residence time then leads to Equation 5:

$$\theta_n = \frac{VC_v}{pC_p} \quad (5)$$

where

p = flow rate of processed sludge leaving the system
C_p = solids concentration in the processed sludge

The subscript p indicates the final product leaving the system, not the underflow from the thickener. This approach ignores any additional residence time in the thickener since this time is relatively short and not at proper digestion conditions.

Sample Calculations

In the following paragraphs, the equations and principles presented above are used to demonstrate the calculation of residence time for several commonly used digester operating modes:

Case 1

- Complete-mix reactor
- Constant feed and withdrawal at least once a day
- No substantial increase or decrease in volume in the reactor (V)
- One or more feed streams and a single product stream (q)

The residence time desired is the nominal residence time. Use Equation 3 as shown below:

$$\theta_n = \frac{VC_v}{qC_q} = \frac{V}{q}$$

The concentration terms in Equation 4 cancel out because C_v equals C_q.

Case 2a

- Complete-mix reactor
- Sludge is introduced in daily batches of volume (V_i) and solids concentration (C_i)
- Vessel contains a "heel" of liquid sludge (V_f) at the beginning of the digestion step
- When final volume (V_f) is reached, sludge is discharged until V_h remains and the process starts again

Some aerobic digesters are run in this fashion. This problem is a special case involving a batch reaction. Exactly how long each day's feeding remains in the reactor is known, but an average residence time must be calculated as shown in Equation 2:

$$\theta_n = \frac{\Sigma v_i C_i \times \text{time that batch i remains in the reactor}}{\Sigma v_i C_i}$$

The following problem illustrates the calculation:

Let V_h = 30 m^3 (volume of "heel")
V_d= 130 m^3 (total digester volume)
V_i = each day 10 m3 is fed to the reactor at the beginning of the day
C_i =12 kg/m^3
V_f is reached in 10 days. Sludge is discharged at the end of Day 10.

$$\text{Then } \theta_n = \frac{(10\cdot12\cdot10+10\cdot12\cdot9+\ldots+10\cdot12\cdot1)}{(10\cdot12+10\cdot12+\ldots 10\cdot12)}$$

$$\theta_n = \frac{10\cdot12\cdot55}{10\cdot12\cdot10} = 5.5 \text{ days}$$

Notice that the volume of the digester or of the "heel" did not enter the calculation.

Case 2b

Same as Case 2a except:

- The solids content of the feed varies substantially from day to day
- Decantate is periodically removed so more sludge can be added to the digester

The following problem illustrates the calculation:

Let V_h = 30m^3, and V_d = 130m^3

Day	V_i (m^3)	Solids Content (kg/m^3)	Decantate (m^3)
1	10	10	0
2	10	15	0
3	10	20	0
4	10	15	0
5	10	15	0
6	10	10	0
7	10	20	0
8	10	25	0
9	10	15	10
10	10	10	0
11	10	15	10
12	10	20	0

$$\theta_n = \frac{(10\cdot10\cdot12+10\cdot15\cdot11+10\cdot20\cdot10+\ldots+10\cdot10\cdot3+10\cdot15\cdot2+10\cdot20\cdot1)}{(10\cdot10+10\cdot15+10\cdot20+\ldots+10\cdot10+10\cdot15+10\cdot20}$$

θ_n = 11,950/1,900 = 6.29d

The volume of "heel" and sludge feedings equaled 150 m^3, exceeding the volume of the digester. This was made possible by decanting 20 m^3.

Case 3

Same as Case 2 except that after the digester is filled it is run in batch mode with no feed or withdrawals for several days.

A conservative θ_n can be calculated by simply adding the number of extra days of operation to the θ_n calculated

for Case 2. The same applies to any other cases followed by batch mode operation.

Case 4

- Complete-mix reactor
- Constant feed and withdrawal at least once a day
- No substantial increase or decrease of volume in the reactor
- One or more feed streams, one decantate stream returned to the treatment works, one product stream; the decantate is removed from the digester so the sludge in the digester is higher in solids than the feed

This mode of operation is frequently used in both anaerobic and aerobic digestion in small treatment works.

Equation 3 is used to calculate the residence time:

Let V=100 m^3
q_f = 10 m^3/d (feed stream)
C_f = 40 kg solids/m^3
q = 5 m^3/d (existing sludge stream)
C_v = 60 kg solids/m^3

$$\theta_n = \frac{100 \times 60}{5 \times 60} = 20 \text{d}$$

Case 5

- Complete-mix reactor
- Constant feed and withdrawal at least once a day
- Volume in digester reasonably constant
- One or more feed streams, one product stream that is thickened, some sludge is recycled, and some is drawn off as product

This mode of operation is sometimes used in aerobic digesters. Equation 5 is used to calculate residence time.

Let V = 100 m^3
Feed flow rate = 10 m^3/d
Feed solids content = 10 kg/m^3
Flow rate from the digester = 12 m^3/d
Solids content of sludge from the digester = 13.3 kg/m^3
Flow rate of sludge from the thickener = 4 m^3/d
Solids content of sludge from the thickener = 40 kg/m^3
Flow rate of sludge returned to the digester = 2 m^3/d
Flow rate of product sludge = 2 m^3/d

$$\theta_n = \frac{100 \times 13.3}{2 \times 40} = 16.6 \text{ d}$$

The denominator is the product of the flow rate leaving the system (2 m^3/d) and the concentration of sludge leaving the thickener (40 kg/m^3). Notice that flow rate of sludge leaving the digester did not enter into the calculation.

Comments on Batch and Staged Operation

Sludge can be aerobically digested using a variety of process configurations (including continuously fed single- or multiple-stage completely mixed reactors), or it can be digested in a batch mode (batch operation may produce less volatile solids reduction for a primary sludge than the other options because there are lower numbers of aerobic microorganisms in it). Single-stage completely mixed reactors with continuous feed and withdrawal are the least effective of these options for bacterial and viral destruction, because organisms that have been exposed to the adverse condition of the digester for only a short time can leak through to the product sludge.

Probably the most practical alternative to use of a single completely mixed reactor for aerobic digestion is staged operation, such as use of two or more completely mixed digesters in series. The amount of slightly processed sludge passing from inlet to outlet would be greatly reduced compared to single-stage operation. If the kinetics of the reduction in pathogen densities are known, it is possible to estimate how much improvement can be made by staged operation.

Farrah et al. (1986) have shown that the declines in densities of enteric bacteria and viruses follow first-order kinetics. If first-order kinetics are assumed to be correct, it can be shown that a one-log reduction of organisms is achieved in half as much time in a two-stage reactor (equal volume in each stage) as in a one-stage reactor. Direct experimental verification of this prediction has not been carried out, but Lee et al. (1989) have qualitatively verified the effect.

It is reasonable to give credit for an improved operating mode. Since not all factors involved in the decay of microorganisms densities are known, some factor of safety should be introduced. It is recommended then that for staged operation using two stages of approximately equal volume, the time required be reduced to 70% of the time required for single-stage aerobic digestion in a continuously mixed reactor. This allows a 30% reduction in time instead of the 50% estimated from theoretical considerations. The same reduction is recommended for batch operation or for more than two stages in series. Thus, the time required would be reduced from 40 days at 20°C (68°F) to 28 days at 20°C (68°F), and from 60 days at 15°C (59°F) to 42 days at 15°C (59°F). These reduced times are also more than sufficient to achieve adequate vector attraction reduction.

If the plant operators desire, they may dispense with the PSRP time-temperature requirements of aerobic digestion but instead demonstrate experimentally that microbial levels in the product from their sludge digester are satisfactorily reduced. Under the current regulations, fecal coliform densities must be less than or equal to 2,000,000 CFU or MPN per gram total solids. Once this performance is demonstrated, the process would have to be operated between monitoring episodes at time-temperature conditions at least as severe as those used during their tests.

Appendix F
Sample Preparation for Fecal Coliform Tests and *Salmonella* sp. Analysis

1. Sample Preparation for Fecal Coliform Tests

1.1 Class B Alternative 1

To demonstrate that a given domestic sludge sample meets Class B Pathogen requirements under alternative 1, the density of fecal coliform from at least seven samples of treated sewage sludge must be determined and the geometric mean of the fecal coliform density must not exceed 2 million Colony Forming Units (CFU) or Most Probable Number (MPN) per gram of total solids (dry weight basis). The solids content of treated domestic sludge can be highly variable. Therefore, an aliquot of each sample must be dried and the solids content determined in accordance with procedure 2540 G. of the 18th edition of Standard Methods for the Examination of Water and Wastewater (SM).

Sludge samples to be analyzed in accordance with SM 9221 E. Fecal Coliform MPN Procedure and 9222 D. Fecal Coliform Membrane Filter Procedure may require dilution prior to analysis. An ideal sample volume will yield results which accurately estimate the fecal coliform density of the sludge. Detection of fecal coliform in undiluted samples could easily exceed the detection limits of these procedures. Therefore, it is recommended that the following procedures be used (experienced analysts may substitute other dilution schemes as appropriate).

For Liquid Samples:

1. Use a sterile graduated cylinder to transfer 30.0 mL of well mixed sample to a sterile blender jar. Use 270 mL of sterile buffered dilution water (see Section 9050C) to rinse any remaining sample from the cylinder into the blender. Cover and blend for two minutes on high speed. 1.0 mL of this mixture is 0.1 mL of the original sample or $1.0X10^{-1}$.

2. Use a sterile pipette to transfer 11.0 mL of the blended sample mixture to 99 mL of sterile buffered dilution in a sterile screw cap bottle and mix by vigorously shaking the bottle a minimum of 25 times. This is dilution "A." 1.0 mL of this mixture is 0.010 mL of the original sample or $1.0X10^{-2}$.

3. Use a sterile pipette to transfer 1.0 mL of dilution "A" to a second screw cap bottle containing 99 mL of sterile buffered dilution water, and mix as before. This is dilution "B." 1.0 mL of this mixture is 0.00010 mL of the original sample or $1.0X10^{-4}$.

4. Use a sterile pipette to transfer 1.0 mL of dilution "B" to a sterile screw cap bottle containing 99 mL of sterile buffered dilution water, and mix as before. This is dilution "C." Go to step 5 for MPN analysis (preferred) or 7 for MF analysis.

5. For MPN analysis, follow procedure 9221 E. in SM. Four series of 5 tubes will be used for the analysis. Inoculate the first series of 5 tubes each with 10.0 mL of dilution "B." This is a 0.0010 mL of the original sample. The second series of tubes should be inoculated with 1.0 mL of dilution "B" (0.00010). The third series of tubes should receive 10.0 mL of "C" (0.000010). Inoculate a fourth series of 5 tubes each with 1.0 mL of dilution "C" (0.0000010). Continue the procedure as described in SM.

6. Refer to Table 9221.IV. in SM to estimate the MPN index/100 mL. Only three of the four series of five tubes will be used for estimating the MPN. Choose the highest dilution that gives positive results in all five tubes, and the next two higher dilutions for your estimate. Compute the MPN/g according to the following equation:

$$\text{MPN Fecal Coliform/g} = \frac{10 \times \text{MPN Index/100 mL}}{\text{largest volume} \times \% \text{ dry solids}}$$

Examples:

In the examples given below, the dilutions used to determine the MPN are underlined. The number in the numerator represents positive tubes; that in the denominator, the total number of tubes planted; the combination of positives simply represents the total number of positive tubes per dilution.

Example	0.0010 mL	0.00010 mL	0.000010 mL	0.0000010 mL	Combination of positives
a	5/5	5/5	3/5	0/5	5-3-0
b	5/5	3/5	1/5	0/5	5-3-1
c	0/5	1/5	0/5	0/5	0-1-0

Item E 000723

For each example we will assume that the total solids content is 4.0%.

For example a:

The MPN index/100 mL from Table 9221.4 is 80. Therefore:

$$MPN/g = \frac{10 \times 80}{0.00010 \times 4.0} = 2.0 \times 10^6$$

For example b:

The MPN index/100 mL from Table 9221.4 is 110. Therefore:

$$MPN/g = \frac{10 \times 110}{0.0010 \times 4.0} = 2.8 \times 10^5$$

For example c:

The MPN index/100 mL from Table 9221.4 is 2. Therefore:

$$MPN/g = \frac{10 \times 2}{0.0010 \times 4.0} = 5.0 \times 10^3$$

5. Alternately the membrane filter procedure may be used to determine fecal coliform density. This method should only be used if comparability with the MPN procedure has been established for the specific sample medium. Three individual filtrations should be conducted in accordance with SM 9222 D. using 10.0 mL of dilution "C," and 1.0 mL and 10.0 mL of dilution "B." These represent 0.000010, 0.00010, and 0.0010 mL of the original sample. Incubate samples, and count colonies as directed. Experienced analysts are encouraged to modify this dilution scheme (e.g. half log dilutions) in order to obtain filters which yield between 20 and 60 CFU.

6. Compute the density of CFU from membrane filters which yield counts within the desired range of 20 to 60 fecal coliform colonies:

$$\text{coliform colonies/g} = \frac{\text{coliform colonies counted} \times 100}{\text{mL sample} \times \% \text{ dry solids}}$$

For Solid Samples:

1. In a sterile dish weigh out 30.0 grams of well mixed sample. Whenever possible, the sample tested should contain all materials which will be included in the sludge. For example, if wood chips are part of a sludge compost, some mixing or grinding means may be needed to achieve homogeneity before testing. One exception would be large pieces of wood which are not easily ground and may be discarded before blending. Transfer the sample to a sterile blender. Use 270 mL of sterile buffered dilution water to rinse any remaining sample into the blender. Cover and blend on high speed for two minutes. One milliliter of this sample contains 0.10 g of the original sample.

2. Use a sterile pipette to transfer 11.0 mL of the blender contents to a screw cap bottle containing 99 mL of sterile buffered dilution water and shake vigorously a minimum of 25 times. One milliliter of this sample contains 0.010 g of the original sample. This is dilution "A."

3. Follow the procedures for "Liquid Samples" starting at Step 3.

Examples:

Seven samples of a treated sludge were obtained prior to land spreading. The solids concentration of each sample was determined according to SM. These were found to be:

Sample No.	Solids Concentration (%)
1	3.8
2	4.3
3	4.0
4	4.2
5	4.1
6	3.7
7	3.9

The samples were liquid with some solids. Therefore the procedure for liquid sample preparation was used. Furthermore, the membrane filter technique was used to determine if the fecal coliform concentration of the sludge would meet the criteria for Class B alternative 1. Samples were prepared in accordance with the procedure outlined above. This yielded 21 individual membrane filters (MF) plus controls. The results from these tests are shown in Table 1

Table 1. Number of Fecal Coliform Colonies on MF Plates

Sample No.	0.000010 mL Filtration	0.00010 mL Filtration	0.0010 mL Filtration
1	0	1	23
2	2	18	TNTC
3	0	8	65
4	0	5	58
5	0	1	17
6	0	1	39
7	0	1	20

The coliform density is calculated using only those MF plates which have between 20 and 60 blue colonies whenever possible. However, there may be occasions when the total number of colonies on a plate will be above or below the ideal range. If the colonies are not discrete and appear to be growing together results should be reported as "too numerous to count" (TNTC). If no filter has a coliform count falling in the ideal range (20 - 60), total the coliform counts on all countable filters and report as coliform colonies/g. For sample number 2 the fecal coliform density is:

$$\text{coliform colonies/g} = \frac{(2+18)\times 100}{(0.000010 + 0.00010) \times 4.3} = 4.2 \times 10^6$$

Sample number 3 has two filters which have colony counts outside the ideal range also. In this case both countable plates should be used to calculate the coliform density/g. For sample number 3, the fecal coliform density is:

$$\text{coliform colonies/g} = \frac{(8 + 65) \times 100}{(0.00010 + 0.0010) \times 4.0} = 1.6 \times 10^6$$

Except for sample number 5, all of the remaining samples have at least one membrane filter within the ideal range. For these samples, use the number of colonies formed on that filter to calculate the coliform density. For sample number 1, the fecal coliform density is:

$$\text{coliform colonies/g} = \frac{23\times 100}{0.0010 \times 3.8} = 6.0 \times 10^5$$

Coliform densities of all the samples were calculated and converted to $\log_{10}$ values to compute a geometric mean. These calculated values are presented in Table 2.

Table 2. Coliform Density of Sludge Samples

Sample No.	Coliform Density	$\log_{10}$
1	6.0×10^5	5.78
2	4.2×10^6	6.63
3	1.6×10^6	6.22
4	1.4×10^5	6.14
5	4.0×10^5	5.60
6	1.0×10^6	6.02
7	5.1×10^5	5.71

The geometric mean for the seven samples is determined by averaging the $\log_{10}$ values of the coliform density and taking the antilog of that value.

$(5.78 + 6.63 + 6.22 + 6.14 + 5.60 + 6.02 + 5.71)/7 = 6.01$

The antilog of $6.01 = 1.03 \times 10^6$

Therefore, the geometric mean fecal coliform density is below 2 million and the sludge meets Class B Pathogen requirements under alternative 1.

1.2 Class A Alternative 1

Part 503 requires that, to qualify as a Class A sludge, treated sewage sludge must be monitored for fecal coliform (or *Salmonella* sp. and have a density of less than 1,000 MPN fecal coliform per gram of total solids (dry weight basis). The regulation does not specify total number of samples. However, it is suggested that a sampling event extend over two weeks and that at least seven samples be collected and analyzed. The membrane filter procedure may not be used for this determination. This is because the high concentration of solids in such sludges may plug the filter or, render the filter uncountable. The total solids content for each sample must be determined in accordance with procedure 2540 G. of SM.

For Liquid Samples:

1. Follow procedure 9221 E. in SM. Inoculate at least four series of five tubes using ten fold serial dilutions. Prepare the sample as described for "Class B Alternative 1, Liquid Samples," except inoculate each of the first series of tubes with 10.0 mL of the blender contents (the concentration of the enrichment broth must be adjusted to compensate for the volume of added sample). This is equivalent to adding 1.0 mL of sludge to the first series of tubes. Inoculate the remaining tubes and complete the analysis in accordance with SM.

2. Calculate the MPN as directed in Step 4 above.

For Solid Samples:

1. Follow procedure 9221 E. in SM. Inoculate at least four series of five tubes using ten fold serial dilutions. Prepare the sample as described for "Class B Alternative 1, Solid Samples," except inoculate each of the first series of tubes with 10.0 mL of the blender contents (the concentration of the enrichment broth must be adjusted to compensate for the volume of added sample). This is equivalent to adding 1.0 g of sludge (wet wieght) to the first series of tubes. Inoculate the remaining tubes and complete the analysis in accordance with SM.

2. Calculate the MPN as directed in step 4 above.

2. Sample Preparation for *Salmonella* sp. Analysis

Salmonella sp. quantification may be used to demonstrate that a sludge meets Class A criteria, instead of analyzing for fecal coliforms. Sludges with *Salmonella* sp. densities below 3 MPN/4 g total solids (dry weight basis) meet Class A criteria. The analytical method described in Appendix F of this document describes the procedure used to identify *Salmonella* sp. in a water sample. Similarly, the procedures for analysis of *Salmonella* sp. in SM (Section 9260 D) do not address procedures for sludges, the sample preparation step described here should be used, and the total solids content of each sample must be determined according to method 2540 G in SM.

For Liquid Samples:

1. Follow the same procedure used for liquid sample preparation for fecal coliform analysis described under "Class A Alternative 1." However, the enrichment medium used for this analysis should be dulcitol selenite broth (DSE) as described in Appendix G of this document or dulcitol selenite or tetrathionate broth as described in SM. Only three series of five tubes should be used for this MPN procedure. Use a sterile open tip pipette to transfer 10.0 mL of well mixed sample to each tube in the first series. These tubes should contain 10.0 mL of double strength enrichment broth. Each tube in the second series should contain 10.0 mL of double strength enrichment broth. These tubes should each receive 10.0

mL of the blended mixture. The final series of tubes should contain 10.0 mL of single strength enrichment broth. These tubes should each receive 1.0 mL of the blended mixture. Complete the MPN procedure as described in Appendix G or SM as appropriate.

2. Refer to Table 9221.IV. in SM to estimate the MPN index/100 mL. Calculate the MPN/4 g according to the following equation:

$$\textit{Salmonella}\text{ sp. MPN/4 g} = \frac{\text{MPN Index/100 mL x 4}}{\text{\% dry solids}}$$

For example:

If one tube in the first series was identified as being positive for *Salmonella* sp. and no other tubes were found to be positive, from Table 9221.IV one finds that a 1-0-0 combination of positives has an MPN index/100 mL of 2. If the percent of dry solids for the sample was 4.0, then:

$$\textit{Salmonella}\text{ sp. MPN/4g} \qquad \frac{2 \text{ x } 4}{4.0} = 2$$

For Solid Samples:

1. Follow the procedure for solid sample preparation for fecal coliform analysis described under Class A Alternative 1 above. However, the enrichment medium used for this analysis should be dulcitol selenite broth (DSE) as described in Appendix G or dulcitol selenite or tetrathionate broth as described in SM, and only three series of five tubes should be used for this MPN procedure. Use aseptic technique to weigh out and transfer 10.0 g of well mixed sample to each screw cap tube in the first series, shake vigorously to mix. These tubes should contain 10.0 mL of double strength enrichment broth. Likewise, each tube in the second series should contain 10.0 mL of double strength enrichment broth. These tubes should receive 10.0 mL of the blended mixture. The final series of tubes should contain 10.0 mL of single strength enrichment broth. These tubes should receive 1.0 mL of the blended mixture. Alternately, because the calculated detection limit is dependent upon the total solids content of the sample, samples with total solids contents >28% can be blended as described above and the blender contents can be used for inoculating the initial series of tubes. When this option is chosen, the final series of tubes will contain 0.1 mL of the blender contents. Complete the MPN procedure as described in Appendix G or SM as appropriate.

2. Refer to Table 9221.IV. in SM to estimate the MPN index/100 mL. Calculate the MPN/4 g according to the following equation:

$$\textit{Salmonella}\text{ sp. MPN/4g} = \frac{\text{MPN Index/1 00mL x 4}}{\text{\% dry solids}}$$

Appendix G
Kenner and Clark (1974) Analytical Method for *Salmonella* sp. Bacteria*

Detection and enumeration of *Salmonella* and *Pseudomonas aeruginosa*

BERNARD A. KENNER AND HAROLD P. CLARK

THE FEDERAL WATER POLLUTION CONTROL AMENDMENTS of 1972 [1-4] may well require the quantification and enumeration of pathogens such as *Salmonella* species in all classes of waters. The requirements are described by Shedroff. [5]

One of the continuing programs of the Environmental Protection Agency (EPA) is a research project concerned with the development of practical laboratory methods for the isolation, quantification, and enumeration of pathogens from polluted waters. This paper reports a monitoring method developed for the simultaneous isolation and enumeration of *Salmonella* species and *Pseudomonas aeruginosa* from potable waters, reuse waters, treatment plant effluents, receiving waters, and sludges.

The method described herein, and developed by Kenner,[6] is practical because readily available bacteriological media, chemicals, and equipment are all that are required to obtain the desired results. These results are the establishment of the absence or presence of *Salmonella* species (pathogenic hazardous bacteria) and/or *Pseudomonas aeruginosa* (potential pathogens) that affect persons who are in a debilitated condition and are very common as infectious agents in hospitals because of their resistance to antibiotic therapy.[7-9] Potable waters have also been shown to contain *Ps. aeruginosa.*[6,10] The sources of these potential pathogens are human and animal feces and wastewaters.[11,12]

When the monitoring method was used, it was found that 100 percent of municipal wastewaters and treatment plant sludges contained both of these potential pathogens. *Ps. aeruginosa* has been found in potable water supplies of large and small municipalities where insufficient residual chlorine is evident. Also important is the fact that these organisms may be found in the absence of fecal coliforms, whereas negative indicator tests may give a false sense of security. It is believed by the authors that these organisms may be better indicators than fecal coliforms of pollution in potable, direct reuse, bathing, and recreational waters.

MATERIALS AND METHODS

The monitoring method uses a multiple tube (MPN) procedure in which dulcitol selenite broth (DSE) [13] is used for primary enrichment medium, and is modified by the use of sodium acid selenite (BBL). The formula is proteose peptone (Bacto), 0.4 percent; yeast extract (Bacto), 0.15 percent; dulcitol, 0.4 percent; BBL, 0.5 percent; Na_2HPO_4, 0.125 percent; and KH_2PO_4, 0.125 percent in distilled water. The constituents are dissolved in a sterile flask, covered with foil, and heated to 88°C in a water bath to obtain a clear sterile medium that does not require adjustment of pH. Productivity for *Salmonella* species is enhanced by the addition of an 18-hr, 37°C culture of *Salmonella paratyphi* A (10 percent by volume) in single-strength DSE broth, killed by heating to 88°C.

Concentration of bacteria from large volumes of water is necessary when potable, direct reuse, receiving waters, and treatment effluents are being monitored.

TABLE I.-Retentive Characteristics of Several Glass Fiber Filter Papers* Compared with Membrane Filters

Filter	Total Bacteria † Filtered	Number Passing Filter	Percentage Retention
Millipore (MF) HAWG 047 HA 0.45 μ, white, grid, 47 mm, Millipore Filter Corp.	1,376	0	100

GF/A Glass Paper Whatman, 47 mm, Reeve Angel Corp.	1,066	680	36

* The 984H Ultra Glass Fiber Filter is flexible when wet, readily allows filtration of large volumes of water, can readily be bent double with forceps, and, when placed into primary enrichment broth, disintegrates when tube is shaken and releases entrapped bacteria.

† Enteric bacteria. *E. coli*, 0.5 X 1-3 μ

‡ A new paper filter GF/F has better retentive properties than the 984H, and has same properties (tested Oct. 1973).

Concentration is attained by filtration through glass fiber filters* in a membrane filter apparatus. After the desired volume of water is filtered through the ultra filter, the flexible filter is folded double with sterile forceps and inserted into a suitable volume of single-strength DSE medium contained in a test tube located in the first row of the multiple tube setup. The tube should then be shaken to cause filter to disintegrate (Table I and Figure 1). To obtain MPN results per one l or per 10 l, 100 ml or 1,000 ml of sample, respectively, are filtered for each tube of DSE medium in the first row of the five-tube MPN setup. Additional dilutions are made by transferring material from tubes in the first row to tubes farther back in the setup.

Obtaining results on a per 1-gal (3.8-l) basis requires filtration of 380 ml, and on a per l0-gal (38-1) basis requires filtration of 3,600 ml for each tube in the first row. Where concentration of bacteria is not usually required, as in municipal wastewaters, sludges, or primary effluents, the regular transfer of 10 ml of sample to each tube in the first row of the setup into 10 ml of double-strength DSE is made, 1 ml of sample in 9 ml of single-strength DSE in the second row, and so on. The MPN table in "Standard Methods"[14] is used to read directly the results per volume of sample.

Incubation temperature of 40° ± 0.2°C for 1 and 2 days is critical to obtain optimum recovery of *Salmonella* sp. and *Pseudomonas aeruginosa* when DSE broth is used for primary enrichment. After primary incubation at 40°C surface loopfuls (scum) (7 mm platinum or nichrome wire loop) are removed from each multiple-tube culture and streaked on each of two sections of a divided plate of Xylose lysine desoxycholate agar (XLD)[15] in order to isolate colonial growth. The numbered plates are inverted and incubated at 37°C for a period not to exceed 24 hr.

Commercial dehydrated XLD agars (BBL and Difco) are satisfactory if they are reconstituted in distilled water in sterile foil-covered flasks and heated to 88° or 92°C, respectively. The agar is then cooled to 55° to 60°C and distributed in sterile petri dishes. This laboratory prefers l0-ml portions in each section of a divided sterile disposable plastic dish (Figure 1).

* Reeve Angel 984H ultra glass fiber filter, 47 mm Reeve Angel & Co., Inc., Clifton, N. J. Mention of trade names does not constitute endorsement or recommendation by EPA.

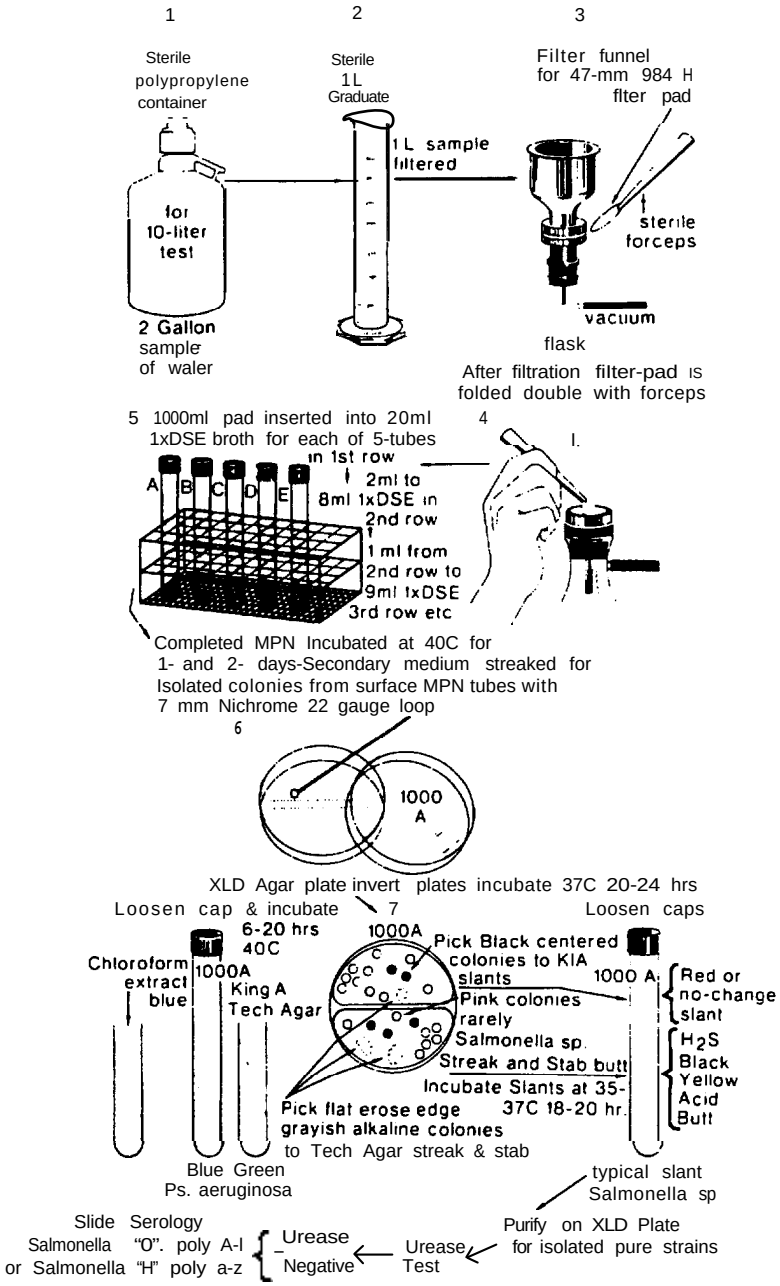

FIGURE I.--Procedure for isolation of pathogens.

Positive incubated XLD plate cultures contain typical clear, pink-edged, black-centered *Salmonella* colonies, and flat, mucoid, grayish alkaline, pink erose-edged *Ps. aeruginosa.* The *Salmonella* colonies are picked to Kligler iron agar (KIA) or Triple sugar iron agar slants for typical appearance, purification, and identity tests. *Ps. aeruginosa* colonies are picked to King A agar slants (Tech agar BBL) for ohtaining the bluegreen pyocyanin confirmation at 40°C (Figure 1).

Typically, *Salmonella* sp. slant cultures (streaked and stabbed), incubated over-

night at 37°C, give an unchanged or alkaline red-appearing slant; the butt is blackened by H_2S, is acid-yellow, and has gas bubbles, except for rare species. Typical-appearing slant cultures are purified by transferring them to **XLD** agar plates for the development of isolated colonies. The flat or umbonated-appearing colonies with large black centers and clear pink edges then are picked to **KIA** slants (streaked and stabbed), incubated at 37°C, and urease tested before the identification procedure (Figure 1). Urease-negative tubes are retained for presumptive serological tests and serotype identification.

Typical Tech agar slant cultures for *Ps. aeruginosa* that are incubated at 40°C overnight turn a bluegreen color from pyocyanin, a pigment produced onIy by this species. A reddish-blue color is caused by the additional presence of pyorubin. The blue pigment is extractable in chloroform and is light blue in color after a few hours at room temperature. No further tests are necessary. The count is read directly from the MPN table.

JUSTIFICATION FOR PROCEDURES

Choice of primary enrichment medium and secondary isolation agar. Most of the enrichment media described in contemporary literature were designed for the isolation of pathogens from clinical specimens from ill persons or from samples of suspected foods, and they work quite well for those types of samples. When they are used, however, for the isolation of pathogens from polluted waters and other types of environmental samples, such as soils, they do not prove adequate. Enrichment media that were tested and found wanting in regard to detection and selectivity were tetrathionate broth (**TT**), with and without brilliant green at 41.5°C; selenite cystine broth at 37°C; selenite F broth at 37°C; selenite brilliant green, with and without sulfa, at 37° and 41.5°C; and Gram-negative broth (**GN**) at 40°C and 41.5°C.

None of the media named worked well at 37°C for the isolation of *Salmonella* sp., and isolation from wastewaters only oc-

curred by chance and was purely qualitative. Of the above-named media used in preliminary tests, selenite brilliant green sulfa broth (SBGS) at 41.5°C gave the best isolation of *Salmonella* sp. from wastewaters (with and without the addition of S. *typhimurium* in known numbers). Of thirteen wastewater samples tested in SBGS at 41.5°C, six contained *Salmonella* or 46 percent were positive. With DSE broth at 40°C, 28 of 28, or 100 percent of wastewater samples, gave positive results.

Studies were not continued on SBGS medium when it was noted that some lots of commercially available SBGS seemed to be selective for *Salmonella* sp. while others were not. The medium was then prepared according to the original formula[16] with six different lots of brilliant green (certified), only one of which was selective. The use of brilliant green agar as a selective medium is subject to the same variability, according to Read and Reyes.[17]

The main reasons for rejection of TT, with and without brilliant green, and for selenite broth's using brilliant green agar and XLD agar as secondary media are not only fewer isolations of *Salmonella* sp., but also the poor selectivity of these combinations when they are used for monitoring polluted waters. These combinations' poor selectivity at 41.5°C is apparent in the results of Dutka and Bell,[18] where the TT broth-XLD combination yielded 26 percent confirmation of colonial picks, and selenite broth-BGA and selenite broth-XLD gave 55 and 56 percent confirmations, respectively. The authors had similar results. The GN-XLD combination was poorest for water samples at 40° and 41.5°C yielding less than 10 percent isolations from wastewaters.

Effect of incubation temperature on isolation of *Salmonella* sp. In a study of 26 wastewater samples that was conducted with the DSE multiple tube setups at three

‡ Serotypes occurring in humans, 1965-1971, Center for Disease Control, Salmonella Surveillance, Annual Summary 1971, Table IX, U. S. DHEW, PHS DHEW Publ. No. (HSM) 73-8184 (Oct. 1972).

different temperatures, it was found that 100 percent of the samples contained *Salmonella* sp. and ***Ps. aeruginosa*** at 40°C. At 41.5°C, however, only 50 percent or 13 of the samples yielded ***Salmonella*** sp., and at 37°C only 8 percent or 2 of the samples yielded ***Salmonella*** sp.

Effect of enhancement of DSE broth with a killed culture of S. *paratyphi* A. In a study of 84 samples of activated sludge effluents, trickling filter effluents, package plant effluents, and stream waters, **DSE** broth enhanced with a killed culture of *S. paratyphi* A in **DSE** broth (10 percent by volume) yielded isolations in 64 samples or 74 percent isolated *Salmonella* sp., compared with 48 samples or 57 percent isolations when the **DSE** broth was used without enhancement. An improved isolation of 17 percent was achieved with enhanced **DSE** broth.

Ultra-filter. The advantages of ultrafilter use in testing water samples are illustrated in Table II.

RESULTS AND DISCUSSION

Of importance to those who must use bacteriological tests to obtain *Salmonella* sp. and ***Ps. aeruginosa*** counts from waters is the amount of work that must be done to secure accurate results. Table III presents the percentage of colony picks made with the described method that proved to be *Salmonella* sp. If there are black-centered colonies on the **XLD** plates, more than 75 percent of the picks will prove to be *Salmonella* sp.; thus, the method leads to less unproductive work. When other methods were used, the authors have at times had to pick 50 black-centered colonies to obtain only 5 *Salmonella* sp. strains. This type of unproductive work has given the search for pathogens in the environment an undeserved bad reputation, and it has caused some to give up.

In Table II it may readily be seen that in many cases the fault with many tests has been the testing of an insufficient volume of sample. Many people think that it involves too much work, and that only expensive fluorescent antibody techniques will work. The problem is, however, to

concentrate the bacteria in a 10-gal (38-l) sample or a l00-gal (380-l) sample of potable or reuse water to obtain results, and still not require even more expensive filtration or centrifugation equipment. It also seems unrealistic to test only extremely small samples of the water being examined, because they may not be representative.

Table IV contains a list of *Salmonella* serotypes isolated from polluted waters and ranked according to the frequency of serotype isolations. It will be noted that all of the serotypes except S. ***typhi*** were isolated from environmental samples by the monitoring method, and that only 6 of the 65 serotypes reported were not reported as occurring in humans in the U. S. over the period from 1965 to 1971.

Table V summarizes the percentage of various types of water samples positive for *Salmonella* sp. Of interest is the fact that 100 percent of the municipal wastewaters tested contain *Salmonella* sp., that 56 percent of chlorinated primary effluents tested contain the pathogens, and that 100 percent of chlorinated secondary effluents are negative for pathogens. There are more studies scheduled for testing of secondary and tertiary effluents to obtain minimal chlorine residuals. Calabro et al.[20] reported that more than 50 attempts at isolating *Salmonella* sp. from septic tank samples using SBGS-BGSA combinations were unsuccessful.

Table VI summarizes the isolation of ***Ps. aeruginosa*** from potable water supply, that is, wells, cisterns, and small municipal water supply. It should be noted that fecal coliforms were not detected in most of these samples. Fecal streptococci counts were higher than fecal coliform counts where both tests were used. ***Ps. aeruginosa*** were present in all but three of the tests, and *Salmonella* sp. were isolated from two different cistern samples.

It is of importance to the user of pathogen tests that the test be quantitative. In initial studies on the DSE-XLD combination, it was important to know if the enrichment broth would support the growth of a wide

range of ***Salmonella*** serotypes. Laboratory cultures of ***S. paratyphi*** A, ***S. typhimurium, S. bredeney, S. oranienberg, S. pullorum, S. anatum, S. give,*** and S. ***worthington*** were tested in three enrichment broths. The time required to isolate each of the above cultures from an estimated 10 to 20 organisms/l00 ml in buffer water was 48 to 72 hr for ***S. paratyphi*** A in TT broth, 24 hr for DSE broth, and 36 to 48 hr for SBGS broth. The rest of the cultures were isolated in estimated numbers in 14 to 24 hr in TT and DSE broths. In SBGS broth, ***S. typhimurium, S. bredeney, S. anatum, S.*** give, and S. ***worthington*** required 36 to 48 hr incubation, and ***S. pullorum*** and S. ***oranienberg*** required 48 to 72 hr incubation.

It is impossible to know if 100 percent of ***Salmonella*** sp. in a polluted water sample are isolated. In tests where laboratory cultures have been added in low numbers to wastewater and treatment effluent samples, all of the numbers added were detected, as well as the ***Salmonella*** sp. that were naturally occurring. The higher the quality of the water (for example, secondary or tertiary treatment effluent, or even potable waters), the better the possibility of isolation of all the *Salmonella* serotypes present, as well as Ps. ***aeruginosa,*** a potential pathogen.

SUMMARY

A practical laboratory method is presented for the simultaneous isolation and enumeration of ***Salmonella*** sp. and *Pseudomonas* ***aeruginosa*** from all classes of waters, including potable water supplies, with a minimum of interfering false positive isolations. The method allows for the testing

of large volumes of high quality waters, wherein the absence of indicator bacteria (that is, total coliforms, fecal coliforms, and fecal streptococci), may give a false sense of security because of the low volumes of water usually tested. Justification for each step of the procedural method is presented.

ACKNOWLEDGMENTS

Credits. The technical assistance of Pauline C. Haley in performing the necessary serology for identifying many of the *Salmonella* serotypes reported is gratefully acknowledged.

Appendix H
Method for the Recovery and Assay of Total Culturable Viruses from Sludge

1. Introduction

1.1. Scope

This chapter describes the method that must be followed to produce Class A sludge when virus monitoring under 40 CFR Part 503 is required. The method is designed to demonstrate that sludges meet the requirement that human enteric viruses (i.e., viruses that are transmitted via the fecal-oral route) are less than one plaque-forming unit (PFU) per 4 g of total dry solids.

1.2. Significance

More than 100 different species of pathogenic human enteric viruses may be present in raw sludge. The presence of these viruses can cause hepatitis, gastroenteritis and numerous other diseases. Hepatitis A virus and noroviruses are the primary human viral pathogens of concern, but standard methods for their isolation and detection have not been developed. The method[1] detailed in this chapter detects total culturable viruses, which primarily include the human enteroviruses (e.g., polioviruses, coxsackieviruses, echoviruses) and reoviruses.

1.3. Safety

The sludges to be monitored may contain pathogenic human enteric viruses. Laboratories performing virus analyses are responsible for establishing an adequate safety plan and must decontaminate and dispose of wastes according to their safety plan and all applicable regulations. Aseptic techniques and sterile materials and apparatus must be used throughout the method.

2. Sample Collection

For each batch of sludge that must be tested for viruses, prepare a composite sample by collecting ten representative samples of 100 mL each (1,000 mL total) from different locations of a sludge pile or at different times from batch or continuous flow processes. Combine and mix thoroughly all representative samples for a composite. Batch samples that cannot be assayed within 24 hours of collection must be frozen at -70°C; otherwise, they should be held at 4°C until processed. If representative samples must be frozen before they can be combined, then thaw, combine and mix them thoroughly just prior to assay. Then remove a 50 mL portion from each composite sample for solids determination as described in section 3. The remaining portion is held at 4°C while the solids determination is being performed or frozen for later processing if the assay cannot be initiated within 8 hours.

Freeze/thawing biosolids may result in some virus loss.

3. Determination of Total Dry Solids[2]

3.1. Weigh a dry weighing pan that has been held in a desiccator and is at a constant weight. Place the 50 mL sludge portion for solids determination into the pan and weigh again.

3.2. Place the pan and its contents into an oven maintained at 103-105°C for at least one hour.

3.3. Cool the sample to room temperature in a desiccator and weigh again.

3.4. Repeat the drying (1 h each), cooling and weighing steps until the loss in weight is no more than 4% of the previous weight.

3.5. Calculate the fraction of total dry solids (T) using the formula:

$$T = \frac{(A - C)}{(B - C)}$$

where A is the weight of the sample and dish after drying, B is the weight of the sample and dish before drying, and C is the weight of the dish. Record the fraction of dry solids (T) as a decimal (e.g., 0.04).

4. Total Culturable Virus Recovery from Sludge

4.1. Introduction

Total culturable viruses in sludge will primarily be associated with solids. Although the fraction of virus associated with the liquid portion will usually be small, this fraction may vary considerably with different sludge types. To correct for this variation, samples will first be treated to

[1]Method D4994-89, ASTM (1992)

[2]Modified from EPA/600/4-84/013(R7), September 1989 Revision (section 3). This and other cited EPA publications may be requested from the Biohazard Assessment Research Branch, National Exposure Research Laboratory, U.S. Environmental Protection Agency, Cincinnati, Ohio, USA 45268.

bind free virus to solids. Virus is then eluted from the solids and concentrated prior to assay.

4.2. Conditioning of Suspended Solids

Conditioning of sludge binds unadsorbed total culturable viruses present in the liquid matrix to the sludge solids.

Each analyzed composite sample (from the portion remaining after solids determination) must have an initial total dry solids content of at least 16 g. This amount is needed for positive controls and for storage of a portion of the sample at -70°C as a backup in case of procedural mistakes or sample cytotoxicity.

4.2.1 Preparation

(a) Apparatus and Materials

(a.1) Refrigerated centrifuge capable of attaining 10,000 ×*g* and screw-capped centrifuge bottles with 100 to 1000 mL capacity.

Each bottle must be rated for the relevant centrifugal force.

(a.2) A pH meter with an accuracy of at least 0.1 pH unit, equipped with a combination-type electrode.

(a.3) Magnetic stirrer and stir bars.

(b) Media and Reagents

Analytical Reagent or ACS grade chemicals (unless specified otherwise) and deionized, distilled water (dH_2O) should be used to prepare all reagents. All water used must have a resistance of greater than 0.5 megohms-cm, but water with a resistance of 18 megohms-cm is preferred.

(b.1) Hydrochloric acid (HCl) — 1 and 5 M.

Mix 10 or 50 mL of concentrated HCl with 90 or 50 mL of dH_2O, respectively.

(b.2) Aluminum chloride ($AlCl_3 \cdot 6H_2O$) — 0.05 M.

Dissolve 12.07 g of aluminum chloride in a final volume of 1000 mL of dH_2O. Autoclave at 121°C for 15 minutes.

(b.3) Sodium hydroxide (NaOH) — 1 and 5 M.

Dissolve 4 or 20 g of sodium hydroxide in a final volume of 100 mL of dH_2O, respectively.

(b.4) Beef extract (Difco Product No. 0115-17-3 or equivalent).

Prepare buffered 10% beef extract by dissolving 10 g beef extract, 1.34 g $Na_2HPO_4 \cdot 7H_2O$ and 0.12 g citric acid in 100 mL of dH_2O. The pH should be about 7.0. Dissolve by stirring on a magnetic stirrer. Autoclave for 15 minutes at 121°C.

Do not use paste beef extract (Difco Laboratories Product No. 0126) for virus elution. This beef extract tends to elute cytotoxic materials from sludges.

(b.5) HOCl — 0.1%

Add 19 mL of household bleach (Clorox, The Clorox Co., or equivalent) to 981 mL of dH_2O and adjust the pH of the solution to 6-7 with 1 M HCl.

(b.6) Thiosulfate — 2% and 0.02%

Prepare a stock solution of 2% thiosulfate by dissolving 20 g of thiosulfate in a total of 1 liter of dH_20. Sterilize the solution by autoclaving at 121°C for 15 minutes. Prepare a working solution of 0.02% thiosulfate just prior to use by mixing 1 mL of 2% thiosulfate with 99 mL of sterile dH_2O.

4.2.2 Conditioning Procedure

Figure 1 gives a flow diagram for the procedure to condition suspended solids.

(a) Calculate the amount of sample to condition.

Use a graduated cylinder to measure the volume. If the volumes needed are not multiples of 100 mL (100, 200, 300 mL, etc.), add sterile water to bring the volume to the next multiple of 100 mL. Each sample should then be aliquoted into 100 mL portions before proceeding. Samples must be mixed vigorously just before aliquoting because solids begin to settle out as soon as the mixing stops. Each aliquot should be placed into a 250 mL beaker containing a stir bar.

CAUTION: Always avoid the formation of aerosols by slowly pouring samples down the sides of vessels.

(a.1) Calculate the amount needed to measure the endogenous total culturable virus in a composite sludge sample using the formula:

$$Xts = \frac{12}{T}$$

where Xts equals the milliliters of sample required to obtain 12 g of total solids and T equals the fraction of total dry solids (from section 3).[3]

(a.2) Calculate the amount needed for a recovery control for each sludge composite from the formula:

$$Xpc = \frac{4}{T}$$

where Xpc equals the milliliters of sample required to obtain 4 g of total solids.

Add 400 plaque forming units (PFU) of a Sabin poliovirus stock to the recovery control sample. Use a virus stock that has been filtered through a 0.2 µm filter (see Section 4.3.1) prior to assay to remove clumped virus particles.

(a.3) Place 30 mL of 10% buffered beef extract and 70 mL of dH_2O into a 250 mL beaker with stir bar to serve as a negative process control.

(a.4) Freeze any remaining composite sample at -70°C for backup purposes.

[3]This formula is based upon the assumption that the density of the liquid in sludge is 1 g/mL. If the fraction of total dry solids is too low (e.g., less than 0.02), then the volume of sludge collected must be increased.

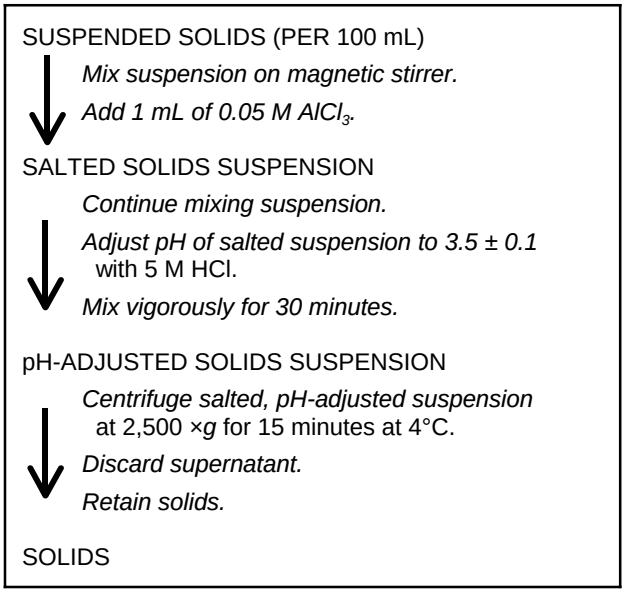

Figure 1. Flow diagram of method for conditioning suspended solids

(b) Perform the following steps on each 100 mL aliquot from steps 4.2.2a.1 to 4.2.2a.3.

(b.1) Place the beaker on a magnetic stirrer, cover loosely with aluminum foil, and stir at a speed sufficient to develop vortex. Add 1 mL of 0.05 M $AlCl_3$ to the mixing aliquot.

The final concentration of $AlCl_3$ in each aliquot is approximately 0.0005 M.

(b.2) Place a combination-type pH electrode into the mixing aliquot. Adjust the pH of the aliquot to 3.5 ± 0.1 with 5 M HCl. Continue mixing for 30 minutes.

The pH meter must be standardized at pH 7 and 4. When solids adhere to an electrode, clean it by moving up and down gently in the mixing aliquot.

After adjusting the pH of each sample, rinse the electrode with dH_2O and sterilize it with 0.1% HOCl for five minutes. Neutralize the HOCl by submerging the electrode in sterile 0.02% thiosulfate for one to five minutes.

The pH of the aliquot should be checked at frequent intervals. If the pH drifts up, readjust it to 3.5 ± 0.1 with 5 M HCl. If the pH drifts down, readjust it with 5 M NaOH. Use 1 M acid or base for small adjustments. Do not allow the pH to drop below 3.4.

(b.3) Pour the conditioned aliquot into a centrifuge bottle and centrifuge at 2,500 ×*g* for 15 minutes at 4°C.

To prevent the transfer of the stir bar into the centrifuge bottle when decanting the aliquot, hold another stir bar or magnet against the bottom of the beaker. Solids that adhere to the stir bar in the beaker may be removed by manipulation with a pipette. It may be necessary to pour the aliquot back and forth several times from the centrifuge bottle to the beaker to obtain all the solids in the bottle. If a large enough centrifuge bottle is available, the test sample aliquots may be combined into a single bottle at this step. If there is more than one recovery control aliquot, they may also be combined into another centrifuge bottle.

(b.4) Decant the supernatant into a beaker and discard. Replace the cap onto the centrifuge bottle. Elute the solids by following the procedure described in section 4.3.

4.3. Elution of Viruses from Solids

4.3.1 Apparatus and Materials

In this and following sections only apparatus and materials which have not been described in previous sections are listed.

(a) Membrane filter apparatus for sterilization — 47 mm diameter Swinnex filter holder and 60 mL slip-tip syringe (Millipore Corp. Product No. SX00 047 00 and Becton Dickinson Product No. 1627 or equivalent).

(b) Disc filters, 47 mm diameter — 3.0, 0.45, and 0.2 µm pore size filters (Mentec America, Filterite Div., Duo- Fine series, Product No. 8025-030, 8025-034 and 8025-037 or equivalent). Filters may be cut to the proper diameter from sheet filters.

Disassemble a Swinnex filter holder. Place the filter with a 0.2 µm pore size on the support screen of the filter holder and stack the remaining filters on top in order of increasing pore size. Reassemble and tighten filter holder. Wrap filter stack in foil and sterilize by autoclaving at 121°C for 15 min.

Filters stacked in tandem as described tend to clog more slowly when turbid material is filtered through them. Prepare several filter stacks.

4.3.2 Elution Procedure

A flow diagram of the virus elution procedure is given in Figure 2.

(a) Place a stir bar and 100 mL of buffered 10% beef extract into the centrifuge bottle containing the solids (from section 4.2.2b.4).

If the test and control samples are divided into more than one centrifuge bottles, the solids should be combined at this step.

Place the centrifuge bottle on a magnetic stirrer, and stir at a speed sufficient to develop a vortex for 30 min at room temperature.

To minimize foaming (which may inactivate viruses), do not mix faster than necessary to develop vortex.

(b) Remove the stir bar from each bottle with a long sterile forceps or a magnet retriever and centrifuge the solids-eluate mixture at 10,000 ×*g* for 30 minutes at 4°C. Decant supernatant fluid (eluate) into a beaker and discard the solids.

Determine if the centrifuge bottle is appropriate for the centrifugal force that will be applied.

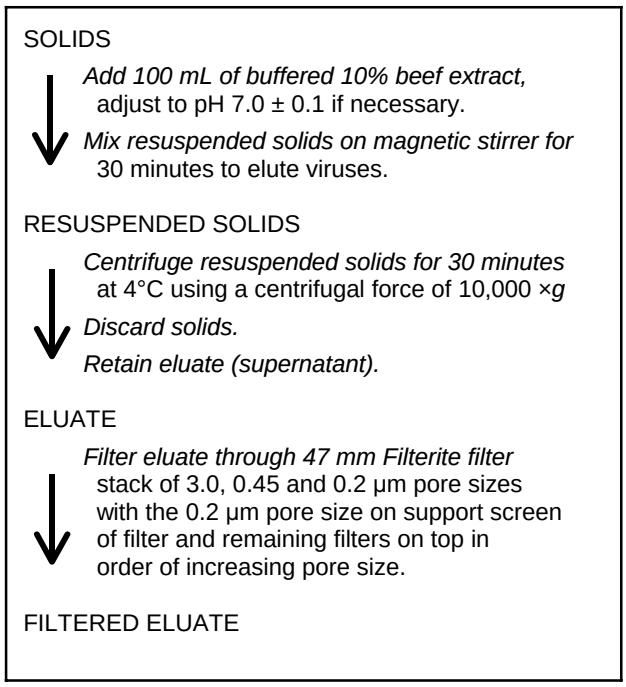

Figure 2. Flow diagram of method for elution of virus from solids.

Centrifugation at 10,000 ×g is normally required to clarify the sludge samples sufficiently to force the resulting supernatant through the filter stacks.

(c) Place a filter holder that contains filter stacks (from section 4.3.1b) onto a 250 mL Erlenmeyer receiving flask. Load 50 mL syringes with the supernatants from step 4.3.2c. Place the tip of the syringe into the filter holder and force the supernatant through the filter stacks into 250 mL receiving flasks.

Prior to use, pass 15 mL of 3% beef extract through each filter holder to minimize non-specific adsorption of viruses. Prepare 3% beef extract by mixing 4.5 mL of 10% beef extract and 10.5 mL of dH_2O. Take care not to break off the tip of the syringe and to minimize pressure on the receiving flask because such pressure may crack or topple the flask. If the filter stack begins to clog badly, empty the loaded syringe into the beaker containing unfiltered eluate, fill the syringe with air, and inject air into filter stack to force residual eluate from the filters. Continue the filtration procedure with another filter holder and filter stack. Discard contaminated filter holders and filter stacks. This procedure may be repeated as often as necessary to filter the entire volume of supernatant. Disassemble each filter holder and examine the bottom 0.2 µm filters to be certain they have not ruptured. If a bottom filter has ruptured, repeat the step with new filter holders and filter stacks.

Proceed immediately to section 4.4.

4.4. Organic Flocculation

This organic flocculation concentration procedure (Katzenelson et al., 1976) is used to reduce the number of cell cultures needed for assays by concentrating total culturable viruses in the eluate. The step significantly reduces costs associated with labor and materials.

Floc formation capacity of the beef extract reagent must be pretested. Because some beef extract lots may not produce sufficient floc, each new lot must be pretested to determine virus recovery. This may be performed by spiking 100 mL of dH_2O with a known amount of poliovirus in the presence of a 47 mm nitrocellulose filter. This sample should be conditioned using section 4.2 above to bind virus to the filter. Virus should then be eluted from the filter using the procedure in section 4.3, and concentrated and assayed using the following procedures. Any lot of beef extract not giving a overall recovery of at least 50% should not be used.

4.4.1 Media and Reagents

In this and following sections only media and reagents which have not been described in previous sections are listed.

(a) Sodium phosphate, dibasic ($Na_2HPO_4 \cdot 7H_2O$) — 0.15 M.

Dissolve 40.2 g of sodium phosphate in a final volume of 1000 mL. Autoclave at 121°C for 15 minutes.

4.4.2 Virus Concentration Procedure

A flow diagram for the virus concentration procedure is given in Figure 3.

(a) Pour the filtered eluates from the test sample, recovery control and negative process control from section 4.3.2d into graduated cylinders, and record their volumes. Transfer the samples into separate 600 mL beakers and cover them loosely with aluminum foil.

(b) For every 3 mL of beef extract eluate, add 7 mL of dH_2O to the 600 mL beakers. Add stir bars to each beaker.

The concentration of beef extract is now 3%. This dilution is necessary because 10% beef extract often does not process well by the organic flocculation concentration procedure.

(c) Record the total volume of the diluted eluates. Place the beakers onto a magnetic stirrer, cover loosely with aluminum foil, and stir at a speed sufficient to develop vortex.

To minimize foaming (which may inactivate viruses), do not mix faster than necessary to develop vortex.

(d) For each diluted, filtered beef extract, insert a sterile combination-type pH electrode and then add 1 M HCl slowly until the pH of the extract reaches 3.5 ± 0.1. Continue to stir for 30 minutes at room temperature.

The pH meter must be standardized at pH 4 and 7. Sterilize the electrode by treating it with 0.1% HOCl for five minutes. Neutralize the HOCl by treating the electrode with 0.02% sterile thiosulfate for one to five minutes.

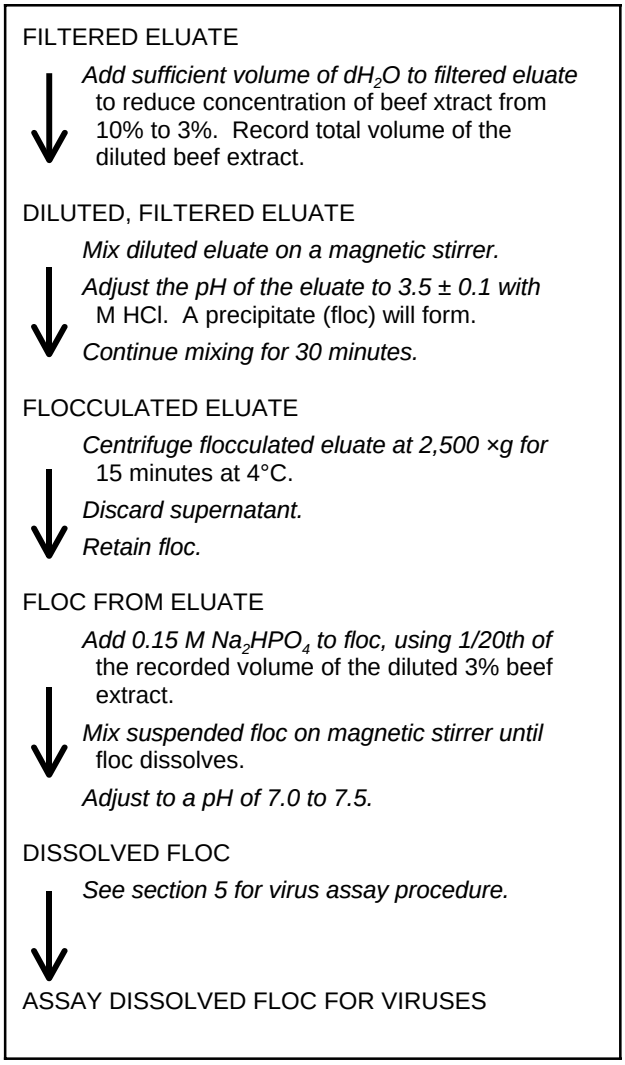

Figure 3. Flow diagram of method for concentration of viruses from beef extract eluate.

A precipitate will form. If the pH is accidentally reduced below 3.4, add 1 M NaOH until it reaches 3.5 ± 0.1. Avoid reducing the pH below 3.4 because some inactivation of virus may occur.

(e) Pour the contents of each beaker into 1,000 mL centrifuge bottles. Centrifuge the precipitated beef extract suspensions at 2,500 ×*g* for 15 minutes at 4°C. Pour off and discard the supernatants.

To prevent the transfer of the stir bar into a centrifuge bottle, hold another stir bar or magnet against bottom of the beaker when decanting contents.

(f) Place stir bars into the centrifuge bottles that contains the precipitates. To each, add a volume of 0.15 M $Na_2HPO_4 \cdot 7H_2O$ equal to exactly 1/20 of the volume recorded in step 4.4.2c. If the precipitate from a sample is in more than one bottle, divide the 1/20th volume equally among the centrifuge bottles containing that sample. Place the bottles onto a magnetic stirrer, and stir slowly until the precipitates have dissolved completely.

Support the bottles as necessary to prevent toppling. Avoid foaming which may inactivate or aerosolize viruses. The precipitates may be partially dissipated with sterile spatulas before or during the stirring procedure.

(g) Measure the pH of the dissolved precipitates.

If the pH is above or below 7.0-7.5, adjust to that range with either 1 M HCl or 1 M NaOH.

(h) Freeze exactly one half of the dissolved precipitate test sample (but not the positive and negative controls) at -70°C. This sample will be held as a backup to use should the sample prove to be cytotoxic. Record the remaining test sample volume (this volume represents 6 g of total dry solids). Refrigerate the remaining samples immediately at 4°C until assayed in accordance with the instructions given in section 5 below.

If the virus assay cannot be undertaken within 24 hours, store the remaining samples at -70°C.

5. Assay for Plaque-forming Viruses[4]

5.1. Introduction

This section outlines procedures for the detection of viruses in sludge by use of the plaque assay system. The system uses an agar medium to localize virus growth following attachment of infectious virus particles to a cell monolayer. Localized lesions of dead cells (plaques) developing some days after viral infection are visualized with the vital stain, neutral red, which stains only live cells. The number of circular unstained plaques are counted and reported as plaque forming units, whose number is proportional to the amount of infectious virus particles inoculated.

The detection methodology presented in this section is geared towards laboratories with a small-scale virus assay requirement. Where the quantities of cell cultures, media and reagents set forth in the section are not sufficient for processing the test sample concentrates, the prescribed measures may be increased proportionally to meet the demands of more expansive test regimes.

5.2. Plaque Assay Procedure

5.2.1 Apparatus and materials.

(a) Waterbath set at 50 ± 1°C.

Used for maintaining the agar temperature (see section 5.2.2j).

5.2.2 Media and Reagents.

(a) ELAH — 0.65% lactalbumin hydrolysate in Earle's base.

Dissolve 6.5 g of tissue culture, highly soluble grade lactalbumin hydrolysate (Gibco BRL Product No. 11800 or

[4]Modified from EPA/600/4-84/013(R11), March 1988 Revision

equivalent) in 1 L of Earle's base (Gibco BRL Product No. 14015 or equivalent) prewarmed to 50-60°C. Sterilize ELAH through a 0.22 μm filter stack and store for up to two months at 4°C.

(b) Wash medium — Add 1 mL of penicillin-streptomycin stock (see section 6.4.2e.1 for preparation of antibiotic stocks), 0.5 mL of tetracycline stock and 0.2 mL of fungizone stock per liter to ELAH immediately before washing of cells.

(c) HEPES — 1 M (Sigma Chemical Product No. H-3375 or equivalent).

Prepare 50 mL of a 1 M solution by dissolving 11.92 g of HEPES in a final volume of 50 mL dH_2O. Sterilize by autoclaving at 121°C for 15 min.

(d) Sodium bicarbonate ($NaHCO_3$) — 7.5% solution.

Prepare 50 mL of a 7.5% solution by dissolving 3.75 g of sodium bicarbonate in a final volume of 50 mL dH_2O. Sterilize by filtration through a 0.22 μm filter.

(e) Magnesium chloride ($MgCl_2 \cdot 6H_20$) — 1.0% solution.

Prepare 50 mL of a 1.0% solution by dissolving 0.5 g of magnesium chloride in a final volume of 50 mL dH_2O. Sterilize by autoclaving at 121°C for 15 min.

(f) Neutral red solution — 0.333%, 100 mL volume (GIBCO BRL Product No. 630-5330 or equivalent).

Procure one 100 mL bottle.

Some neutral red solutions are cytotoxic. All new solutions should be tested prior to their use for assaying sludge samples. Testing may be performed by assaying a stock of poliovirus with known titer using this plaque assay procedure.

(g) Bacto skim milk (Difco Laboratories Product No. 0032-01 or equivalent).

Prepare 100 mL of 10% skim milk in accordance with directions given by manufacturer.

(h) Preparation of Medium 199.

The procedure described is for preparation of 500 mL of Medium 199 (GIBCO BRL Product No. 400-1100 or equivalent) at a 2X concentration. This procedure will prepare sufficient medium for at least fifty 6 oz glass bottles or eighty 25 cm^2 plastic flasks.

(h.1) Place a three inch stir bar into a one liter flask. Add the contents of a 1 liter packet of Medium 199 into the flask. Add 355 mL of dH_2O. Rinse medium packet with three washes of 20 mL each of dH_2O and add the washes to the flask.

Note that the amount of dH_2O is 5% less than desired final volume of medium.

(h.2) Mix on a magnetic stirrer until the medium is completely dissolved. Filter the reagent under pressure through a filter stack (see section 6.2.6).

Test each lot of medium to confirm sterility before the lot is used (see section 6.5). Each batch may be stored for two months at 4°C.

(i) Preparation of overlay medium for plaque assay.

The procedure described is for preparation of 100 mL of overlay medium and will prepare sufficient media for at least ten 6 oz glass bottles or twenty 25 oz plastic flasks when mixed with the agar prepared in section 5.2.2j.

(i.1) Add 79 mL of Medium 199 (2X concentration) and 4 mL of serum to a 250 mL flask.

(i.2) Add the following to the flask in the order listed, with swirling after each addition: 6 mL of 7.5% $NaHCO_3$, 2 mL of 1% $MgCl_2$, 3 mL of 0.333% neutral red solution, 4 mL of 1 M HEPES, 0.2 mL of penicillin-streptomycin stock (see section 6.4.2e for a description of antibiotic stocks), 0.1 mL of tetracycline stock, and 0.04 mL of fungizone stock.

(i.3) Place flask with overlay medium in waterbath set at 36 ± 1°C.

(j) Preparation of overlay agar for plaque assay.

(j.1) Add 3 g of agar (Sigma Chemical Product No. A-9915 or equivalent) and 100 mL of dH_2O to a 250 mL flask. Melt by sterilizing the agar solution in an autoclave at 121°C for 15 min.

(j.2) Cool the agar to 50°C in waterbath set at 50 ± 1°C.

(k) Preparation of agar overlay medium.

(k.1) Add 2 mL of 10% skim milk to overlay medium prepared in section 5.2.2i.

(k.2) Mix equal portions of overlay medium and agar by adding the medium to the agar flask.

To prevent solidification of the liquified agar, limit the portion of agar overlay medium mixed to that volume which can be dispensed in 10 min.

5.2.3 Procedure for Inoculating Test Samples.

Section 6.6 provides the procedures for the preparation of cell cultures used for the virus assay in this section.

BGM cell cultures used for virus assay are generally found to be at their most sensitive level between the third and sixth days after initiation. Those older than seven days or which are not 100% confluent should not be used.

(a) Decant and discard the growth medium from previously prepared cell culture test vessels.

To prevent splatter, a gauze-covered beaker may be used to collect spent medium.

The medium is changed from one to four hours before cultures are to be inoculated and carefully decanted so as not to disturb the cell monolayer.

(b) Replace discarded medium with an equal volume of wash medium (from section 5.2.2b) on the day the cultures are to be inoculated.

Table 1. Guide for Virus Inoculation, Suspended Cell Concentration and Overlay Volume of Agar Medium

Vessel Type	Volume of Virus Inoculum (mL)	Volume of Agar Overlay Medium (mL)	Total Number of Cells
1 oz glass bottle[1]	0.1	5	1×10^7
25 cm^2 plastic flask	0.1-0.5	10	2×10^7
6 oz glass bottle	0.5-1.0	20	4×10^7
75 cm^2 plastic flask	1.0-2.0	30	6×10^7

[1]Size is given in oz only when it is commercially designated in that unit.

To reduce shock to cells, prewarm the wash medium to 36.5 ± 1°C before placing it onto the cell monolayer.

To prevent disturbing cells with the force of the liquid against the cell monolayer, add the wash medium to the side of cell culture test vessel opposite the cell monolayer.

(c) Identify cell culture test vessels by coding them with an indelible marker. Return the cell culture test vessels to a 36.5 ± 1°C incubator and hold at that temperature until the cell monolayers are to be inoculated.

(d) Decant and discard the wash medium from cell culture test vessels.

Do not disturb the cell monolayer.

(e) Inoculate BGM cultures with the test sample and positive and negative process control samples from section 4.4.2h. Divide each sample onto a sufficient number of BGM cultures to ensure that the inoculum volume is no greater than 1 mL for each 40 cm^2 of surface area. Use Table 1 as a guide for inoculation size.

Avoid touching either the cannula or the pipetting device to the inside rim of the cell culture test vessels to avert the possibility of transporting contaminants to the remaining culture vessels.

If the samples are frozen, thaw them rapidly by placing them in warm water. Samples should be shaken during the thawing process and removed from the warm water as soon as the last ice crystals have dissolved.

(e.1) Inoculate BGM cultures with the entire negative process control sample using an inoculum volume per vessel that is appropriate for the vessel size used.

(e.2) Inoculate two BGM cultures with an appropriate volume of 0.15 M $Na_2HPO_4 \cdot 7H_2O$ preadjusted to pH 7.0-7.5 and seeded with 20-40 PFU of poliovirus. These cultures will serve as a culture sensitivity control.

(e.3) Remove a volume of the test sample concentrate exactly equal to 1/6th (i.e., 1 g of total dry solids) of the volume recorded in section 4.4.2h. Seed this subsample with 20-40 PFU of poliovirus. Inoculate the subsample onto one or more BGM cultures using a inoculum volume per vessel that is appropriate for the vessel size used. These cultures will serve as controls for cytotoxicity (see section 5.2.5b).

(e.4) Inoculate BGM cultures with the entire recovery control sample using an inoculum volume per vessel that is appropriate for the vessel size used.

(e.5) Record the volume of the remaining 5/6th portion of the test sample. This remaining portion represents a total dry solids content of 5 g. Inoculate the entire remaining portion (even if diluted to reduce cytotoxicity) onto BGM cultures using an inoculum volume per vessel that is appropriate for the vessel size used. Inoculation of the entire volume is necessary to demonstrate a virus density level of less than 1 PFU per 4 g total dry solids.

(f) Rock the inoculated cell culture test vessels gently to achieve uniform distribution of inoculum over the surface of the cell monolayers. Place the cell culture test vessels on a level stationary surface at room temperature (22- 25°C) so that the inoculum will remain distributed evenly over the cell monolayer.

(g) Incubate the inoculated cell cultures at room temperature for 80 min to permit viruses to adsorb onto and infect cells and then proceed immediately to section 5.2.4.

It may be necessary to rock the vessels every 15-20 min during the 80 min incubation to prevent cell death in the middle of the vessels from dehydration.

5.2.4 Procedure for Overlaying Inoculated Cultures with Agar.

If there is a likelihood that a test sample will be toxic to cell cultures, the cell monolayer should be treated in accordance with the method described in section 5.2.5b.

(a) To each cell culture test vessel, add the volume of warm (42-46°C) agar overlay medium appropriate for the cell surface area of the vessels used (see Table 1).

The preparation of the overlay agar and the agar overlay medium must be made far enough in advance so that they will be at the right temperature for mixing at the end of the 80 min inoculation period.

To prevent disturbing cells with the force of the liquid against the cell monolayer, add the agar overlay medium to the side of the cell culture test vessel opposite the cell monolayer.

(b) Place cell culture test vessels, monolayer side down, on a level stationary surface at room temperature (22-25°C) so that the agar will remain evenly distributed as it solidifies. Cover the vessels with a sheet of aluminum foil, a tightly woven cloth, or some other suitable cover to reduce the light intensity during solidification and incubation. Neutral red can damage or kill tissue culture cells by light-induced crosslinking of nucleic acids.

Care must be taken to ensure that all caps on bottles and flasks are tight; otherwise, the gas seal will not be complete and an erroneous virus assay will result.

Agar will fully solidify within 30 min.

(c) After 30 min, invert the cell culture test vessels and incubate them covered in the dark at 36.5 ± 1°C.

5.2.5 Plaque Counting Technique.

(a) Count, mark and record plaques in cell culture test vessels on days one, two, three, four after adding the agar overlay medium. Plaques should be counted quickly using a lightbox (Baxter Product No. B5080-1 or equivalent) in a darkened room. Most plaques should appear within 1 week.

Depending on the virus density and virus types present in the inoculated sample, rescheduling of virus counts at plus or minus one day may be necessary. Virus titers are calculated from the total plaque count. Note that not all plaques will be caused by viruses.

(b) Determine if samples are cytotoxic by macroscopic examination of the appearance of the cell culture monolayer (compare negative, positive and recovery controls from section 5.2.3e with seeded and unseeded test samples) after one to four days of incubation at 36.5 ± 1°C. Samples show cytotoxicity if cell death is observed on test and recovery control samples prior to its development on positive controls. Cytotoxicity should be suspected when the agar color is more subdued, generally yellow to yellow-brown. This change in color results in a mottled or blotchy appearance instead of the evenly diffused "reddish" color observed in "healthy" cell monolayers. Cytotoxicity may also cause viral plaques to be reduced in number or to be difficult to distinguish from the surrounding monolayer. To determine if this type of cytotoxicity is occurring, compare the two types of positive controls (section 5.2.3e). If samples are cytotoxic, do not proceed to the next steps. Re-assay a small amount of the remaining sample using 1:2, 1:4 and 1:8 dilutions. Then re-assay the remaining sample as specified in section 5.2.3 using the dilution which removes cytotoxicity and the specified number of flasks times the reciprocal of the dilution.

A small amount of sample may be tested for cytotoxicity prior to a full assay.

(c) Examine cell culture test vessels as in step 5.2.5a on days six, eight, twelve and sixteen.

If no new plaques appear at 16 days, proceed with step 5.2.6; otherwise continue to count, mark and record plaques every two days until no new plaques appear between counts and then proceed with step 5.2.6.

Inoculated cultures should always be compared to uninoculated control cultures so that the deterioration of the cell monolayers is not recorded as plaques. If experience shows that cultures start to deteriorate prior to 16 days, a second layer of agar can be added after 7 days as described in section 5.2.4.

If negative process controls develop plaques or if positive controls fail to develop plaques, stop all assays until the source of the problem is corrected.

Samples giving plaque counts that are greater than 2 plaques per cm^2 should be diluted and replated.

5.2.6 Virus Plaque Confirmation Procedure

The presence of virus in plaques must be confirmed for all plaques obtained from sludge samples. Where more than ten plaques are observed, it is allowable to confirm at least ten well-separated plaques per sample or 10% of the plaques in a sample, whichever is greater. Flasks may be discarded after samples are taken for plaque confirmation.

(a) Apparatus, Materials and Reagents

(a.1) Pasteur pipettes, disposable, cotton plugged — 229 mm (9 inches) tube length and rubber bulb — 1 mL capacity.

Flame each pipette gently about 2 cm from end of the tip until the tip bends to an approximate angle of 45°. Place the pipettes into a 4 liter beaker covered with aluminum foil and sterilize by autoclaving or by dry heat.

(a.2) 16 x 150 mm cell culture tubes containing BGM cells.

See section 6.6 for the preparation of cell culture tubes.

(a.3) Tissue culture roller apparatus — 1/5 rpm speed (New Brunswick Scientific Product No. TC-1 or equivalent) with culture tube drum for use with roller apparatus (New Brunswick Scientific Product No. ATC-TT16 or equivalent).

(a.4) Freezer vial, screw-capped (with rubber insert) or cryogenic vial — 0.5-1 dram capacity.

(b) Procedure for obtaining viruses from plaque.

In addition to plaques from sludge samples, perform the procedure on at least three negative regions of negative process control flasks and at least three plaques from positive control flasks.

(b.1) Place a rubber bulb onto the upper end of a cotton-plugged Pasteur pipette and then remove the screw-cap or stopper from a plaque bottle.

(b.2) Squeeze the rubber bulb on the Pasteur pipette to expel the air and penetrate the agar directly over the edge of a plaque with the tip of the pipette. Gently force the tip of the pipette through the agar to the surface of the vessel, and scrape some of the cells from the edge of the plaque.

Repeatedly scratch the surface and use gentle suction to insure that virus-cell-agar plug enters the pipette.

(b.3) Remove the pipette from the plaque bottle and tightly replace the cap or stopper.

(c) Procedure for inoculating cell cultures with agar plugs from negative control samples and from plaques.

(c.1) Prepare plaque conformation maintenance medium by adding 5 mL of serum and 5 mL of dH_2O per 90 mL of wash medium (section 5.2.2b) on day samples are to be tested.

(c.2) Pour the spent medium from cell culture tubes and discard the medium. Replace the discarded medium with 2

mL of the plaque conformation maintenance medium. Label the tubes with sample and plaque isolation identification information.

To prevent splatter, a gauze-covered beaker may be used to collect spent medium.

To reduce shock to cells, warm the maintenance medium to 36.5 ± 1°C before placing on cell monolayer.

To prevent disturbing cells with the force of the liquid against the cell monolayer, add the maintenance medium to the side of cell culture test tube opposite the cell monolayer. Note that cells will be only on the bottom inner surface of the culture tube relative to their position during incubation.

(c.3) Remove the cap from a cell culture tube and place the tip of a Pasteur pipette containing the agar plug from section 5.2.6b.3 into the maintenance medium in the cell culture tube. Force the agar plug from the Pasteur pipette by gently squeezing the rubber bulb. Withdraw and discard the pipette, and replace and tighten down the screw-cap on the culture tube.

Tilt cell culture tube as necessary to facilitate the procedure and to avoid scratching the cell sheet with the pipette.

Squeeze bulb repeatedly to wash contents of pipette into the maintenance medium.

(c.4) Place the cell culture tubes in the drum used with the tissue culture roller apparatus. Incubate the cell cultures at 36.5 ± 1°C while rotating at a speed of 1/5 rpm. Examine the cells daily microscopically for 1 week for evidence of cytopathic effects (CPE).

CPE may be identified as cell disintegration or as changes in cell morphology. Rounding-up of infected cells is a typical effect seen with enteric virus infections. However, uninfected cells round up during mitosis and a sample should not be considered positive unless there are significant clusters of rounded-up cells over and beyond what is observed in the uninfected controls. If there is any doubt about the presence of CPE or if CPE appears late (i.e., on day 6 or 7), the conformation process should be repeated by transferring 0.2 mL of the medium in the culture tube to a freshly prepared tube.

Incubation of BGM cells in roller apparatus for periods greater than 1 week is not recommended as cells under these conditions tend to die-off if held longer.

If tubes receiving agar plugs from negative controls develop CPE or tubes receiving agar plugs from positive controls fail to develop CPE, stop all assays until the source of the failure is identified and corrected.

Tubes developing CPE may be stored in a -70°C freezer for additional optional tests (e.g., the Lim Benyesh-Melnick identification procedure.[5]

(c.5) Determine the fraction of confirmed plaques (C) for each sludge sample tested. Calculate "C" by dividing the number of tubes inoculated with agar plugs from plaques that developed CPE by the total number of tubes inoculated (i.e., if CPE was obtained from 17 of 20 plaques, C = 0.85).

5.2.7 Calculation of virus titer.

If more than one composite sample was assayed, average the titer of all composite samples and report the average titer and the standard deviation for each lot of sludge tested.

(a) If the entire remaining portion of a test sample was inoculated onto BGM cultures as described in section 5.2.3e.5, calculate the virus titer (V) in PFU per 4 g of total dry solids according to the formula:

$$V = 0.8 \times P \times C$$

where P is the total number of plaques in all test vessels for that sample and C equals the fraction of confirmed plaques.

(b) If the sample was diluted due to high virus levels (e.g., when the virus density of the input to a process is being determined; see section 5.2.5c), calculate the virus titer (V) in PFU per 4 g total dry solids with the formula:

$$V = 0.8 \times \frac{P}{I} \times D \times S \times C$$

where P is the total number of plaques in all test vessels for dilution series, I is the volume (in mL) of the dilution inoculated, D is reciprocal of the dilution made on the inoculum before plating, S is the volume of the remaining portion of the test sample (as recorded in section 5.2.3e.5) and C is the fraction of confirmed plaques.

5.2.8 Calculate the percent of virus recovery (R) using the formula:

$$R = \frac{P}{400} \times 100$$

where P is the total number of plaques on all test vessels inoculated with the recovery control.

6. Cell Culture Preparation and Maintenance[6]

6.1. Introduction

This section outlines procedures and media for culturing the Buffalo Green monkey (BGM) kidney cell line and is intended for the individual who is experienced in cell culture preparation. BGM cells are a continuous cell line derived from African Green monkey kidney cells. The characteristics of this line were described by Barron et al. (1970). Use of BGM cells for recovering viruses from environmental samples was described by Dahling et al. (1974). The media and methods recommended are the results of the BGM cell line optimization studies by Dahling and Wright (1986). The BGM cell line can be obtained by qualified laboratories from the Biohazard Assessment Research Branch, National Exposure Research Laboratory, U. S. Environmental Protection Agency, Cincinnati, Ohio, USA 45268. Although BGM

[5]For more information see EPA/600/4-84/013(R12), May 1988 Revision

[6]Modified from EPA/600/4-84/013(R9), January 1987 Revision

cells will not detect all enteric viruses that may be present in sludges, the use of this cell line alone is sufficient to meet the requirements of 40 CFR Part 503.

6.2. Apparatus and Materials

6.2.1 Glassware, Pyrex (Corning Product No. 1395 or equivalent).

Storage vessels must be equipped with airtight closures.

6.2.2 Autoclavable inner-braided tubing with metal quick-connect connectors or with screw clamps for connecting tubing to equipment to be used under pressure.

Quick-connect connectors can be used only after equipment has been properly adapted.

6.2.3 Positive pressure air, nitrogen or 5% CO_2 source equipped with pressure gauge.

Pressure sources from laboratory air lines and pumps must be equipped with an oil filter. The source must not deliver more pressure to the pressure vessel than is recommended by manufacturer.

6.2.4 Dispensing pressure vessel — 5 or 20 liter capacity (Millipore Corp. Product No. XX67 00P 05 and XX67 00P 20 or equivalent).

6.2.5 Disc filter holders — 142 mm or 293 mm diameter (Millipore Corp. Product No. YY30 142 36 and YY30 293 16 or equivalent).

Use only pressure type filter holders.

6.2.6 Sterilizing filter stacks — 0.22 µm pore size (Millipore Corp. Product No. GSWP 142 50 and GSWP 293 25 or equivalent). Fiberglass prefilters (Millipore Corp. Product No. AP15 142 50 or AP15 293 25 and AP20 142 50 or AP20 293 25 or equivalent).

Stack AP20 and AP15 prefilters and 0.22 µm membrane filter into a disc filter holder with AP20 prefilter on top and 0.22 µm membrane filter on bottom.

Always disassemble the filter stack after use to check the integrity of the 0.22 µm filter. Refilter any media filtered with a damaged stack.

6.2.7 Positively-charged cartridge filter — 10 inch (Zeta plus TSM, Cuno Product No. 45134-01-600P or equivalent). Holder for cartridge filter with adaptor for 10 inch cartridge (Millipore Corp. Product No. YY16 012 00 or equivalent).

6.2.8 Culture capsule filter (Gelman Sciences Product No. 12140 or equivalent).

6.2.9 Cell culture vessels — Pyrex, soda or flint glass or plastic bottles and flasks or roller bottles (e.g., Brockway Product No. 1076-09A, 1925-02, Corning Product No. 25100-25, 25110-75, 25120-150, 25150-1750 or equivalent).

Vessels must be made from clear glass or plastic to allow observation of the cultures and be equipped with airtight closures. Plastic vessels must be treated by the manufacturer to allow cells to adhere properly.

6.2.10 Screw caps, black with rubber liners (Brockway Product No. 24-414 for 6 oz bottles[7] or equivalent).

Caps for larger culture bottles usually supplied with bottles.

6.2.11 Roller apparatus (Bellco Product No. 7730 or equivalent).

6.2.12 Incubator capable of maintaining the temperature of cell cultures at 36.5 ± 1°C.

6.2.13 Waterbath, equipped with circulating device to assure even heating at 36.5 ± 1°C.

6.2.14 Light microscope, with conventional light source, equipped with lenses to provide 40X, 100X, and 400X total magnification.

6.2.15 Inverted light microscope equipped with lenses to provide 40X, 100X, and 400X total magnification.

6.2.16 Cornwall syringe pipettors, 2, 5 and 10 mL sizes (Curtin Matheson Scientific Product No. 221-861, 221-879, and 221-887 or equivalent).

6.2.17 Brewer-type pipetting machine (Curtin Matheson Scientific Product No. 138-107 or equivalent).

6.2.18 Phase contrast counting chamber (hemocytometer) (Curtin Matheson Scientific Product No. 158-501 or equivalent).

6.2.19 Conical centrifuge tubes, sizes 50 mL and 250 mL.

6.2.20 Rack for tissue culture tubes (Bellco Product No. 2028 or equivalent).

6.2.21 Bottles, aspirator-type with tubing outlet, size 2,000 mL.

Bottles for use with pipetting machine.

6.2.22 Storage vials, size 2 mL.

Vials must withstand temperatures to -70°C.

6.3. Media and Reagents

6.3.1 Sterile fetal calf, gammagobulin-free newborn calf or iron-supplemented calf serum, certified free of

[7]Size is given in oz only when it is commercially designated in that unit.

viruses, bacteriophage and mycoplasma (GIBCO BRL or equivalent).

Test each lot of serum for cell growth and toxicity before purchasing. Serum should be stored at -20°C for long-term storage. Upon thawing, each bottle should be heat-inactivated at 56°C for 30 min and stored at 4°C for short term use.

6.3.2 Trypsin, 1:250 powder (Difco Laboratories Product No. 0152-15-9 or equivalent) or trypsin, 1:300 powder (BBL Microbiology Systems Product No. 12098 or equivalent).

6.3.3 Sodium (tetra) ethylenediamine tetraacetate powder (EDTA), technical grade, (Fisher Scientific Product No. S657-500 or equivalent).

6.3.4 Thioglycollate medium (Difco Laboratories Product No. 0257-01-9 or equivalent).

6.3.5 Fungizone (amphotericin B, Sigma Chemical Product No. A-9528 or equivalent), Penicillin G (Sigma Chemical Product No. P-3032 or equivalent), dihydrostreptomycin sulfate (ICN Biomedicals Product No. 100556 or equivalent), and tetracycline (ICN Biomedicals Product No. 103011 or equivalent).

Use antibiotics of at least tissue culture grade.

6.3.6 Eagle's minimum essential medium (MEM) with Hanks' salts and L-glutamine, without sodium bicarbonate (GIBCO BRL Product No. 410-1200 or equivalent).

6.3.7 Leibovitz's L-15 medium with L-glutamine (GIBCO BRL Product No. 430-1300 or equivalent).

6.3.8 Trypan blue (Sigma Chemical Product No. T-6146 or equivalent).

Note: This chemical is on the EPA list of proven or suspected carcinogens.

6.3.9 Dimethyl sulfoxide (DMSO; Sigma Chemical Product No. D-2650 or equivalent).

6.3.10 Mycoplasma testing kit (Irvine Scientific Product No. T500-000 or equivalent).

6.4. Preparation of Cell Culture Media

6.4.1 General Principles

(a) Equipment care — Carefully wash and sterilize equipment used for preparing media before each use.

(b) Disinfection of work area — Thoroughly disinfect surfaces on which the medium preparation equipment is to be placed. Many commercial disinfectants do not adequately kill total culturable viruses. To ensure thorough disinfection, disinfect all surfaces and spills with either a solution of 0.5% (5 g per liter) iodine in 70% ethanol or 0.1% HOCl.

(c) Aseptic technique — Use aseptic technique when preparing and handling media or medium components.

(d) Dispensing filter-sterilized media — To avoid post-filtration contamination, dispense filter-sterilized media into storage containers through clear glass filling bells in a microbiological laminar flow hood. If a hood is unavailable, use an area restricted solely to cell culture manipulations.

(e) Coding media — Assign a lot number to and keep a record of each batch of medium or medium components prepared. Place the lot number, the date of preparation, the expiration date, and the initials of the person preparing the medium on each bottle.

(f) Sterility test — Test each lot of medium and medium components to confirm sterility as described in section 6.5 before the lot is used for cell culture.

(g) Storage of media and medium components — Store media and medium components in clear airtight containers at 4°C or -20°C as appropriate.

(h) Sterilization of $NaHCO_3$-containing solutions — Sterilize media and other solutions that contain $NaHCO_3$ by positive pressure filtration.

Negative pressure filtration of such solutions increases the pH and reduces the buffering capacity.

6.4.2 Media Preparation Recipes

(a) Sources of cell culture media — Commercially prepared liquid cell culture media and medium components are available from several sources. Cell culture media can also be purchased in powder form that requires only dissolution in dH_2O and sterilization. Media from commercial sources are quality-controlled. The conditions specified by the supplier for storage and expiration dates should be strictly observed. However, media can also be prepared in the laboratory directly from chemicals. Such preparations are labor intensive, but allow quality control of the process at the level of the preparing laboratory.

(b) Procedure for the preparation of EDTA-trypsin.

The procedure described is for the preparation of 10 liters of EDTA-trypsin reagent. It is used to dislodge cells attached to the surface of culture bottles and flasks. This reagent, when stored at 4°C, retains its working strength for at least four months. The amount of reagent prepared should be based on projected usage over a four-month period.

(b.1) Add 30 g of trypsin (1:250) or 25 g of trypsin (1:300) and two liters of dH_2O to a six liter flask containing a three inch stir bar. Place the flask onto a magnetic stirrer and mix the trypsin solution rapidly for a minimum of one hour.

Trypsin remains cloudy.

(b.2) Add four liters of dH_2O and a three-inch stir bar into 20 liter clear plastic carboy. Place the carboy onto a magnetic stirrer and stir at a speed sufficient to develop a vortex while adding the following chemicals: 80 g NaCl, 12.5 g

EDTA, 50 g dextrose, 11.5 g $Na_2HPO_4 \cdot 7H_2O$, 2.0 g KCl, and 2.0 g KH_2PO_4.

Each chemical does not have to be completely dissolved before adding the next one.

(b.3) Add four more liters of dH_2O to carboy.

Continue mixing until all chemicals are completely dissolved.

(b.4) Add the two liters of trypsin from step 6.4.2b.1 to the prepared solution in step 6.4.2b.3 and mix for a minimum of one hour. Adjust the pH of the EDTA-trypsin reagent to 7.5 - 7.7.

(b.5) Filter reagent under pressure through a disc filter stack and store the filtered reagent in tightly stoppered or capped containers at 4°C.

The cartridge prefilter (section 6.2.7) can be used in line with the culture capsule sterilizing filter (section 6.2.8) as an alternative to a filter stack (section 6.2.6).

(c) Procedure for the preparation of MEM/L-15 medium.

The procedure described is for preparation of 10 liters of MEM/L-15 medium.

(c.1) Place a three inch stir bar and four liters of dH_2O into 20 liter carboy.

(c.2) Place the carboy onto a magnetic stirrer. Stir at a speed sufficient to develop a vortex and then add the contents of a five liter packet of L-15 medium to the carboy. Rinse the medium packet with three washes of 200 mL each of dH_2O and add the rinses to the carboy.

(c.3) Mix until the medium is evenly dispersed.

L-15 medium may appear cloudy as it need not be totally dissolved before proceeding to step 6.4.2c.4.

(c.4) Add three liters of dH_2O to the carboy and the contents of a five liter packet of MEM medium to the carboy. Rinse the MEM medium packet with three washes of 200 mL each of dH_2O and add the rinses to the carboy. Add 800 mL of dH_2O and 7.5 g of $NaHCO_3$ and continue mixing for an additional 60 min.

(c.5) Transfer the MEM/L-15 medium to a pressure can and filter under positive pressure through a 0.22 µm sterilizing filter. Collect the medium in volumes appropriate for the culturing of BGM cells (e.g., 900 mL in a 1 liter bottle) and store in tightly stoppered or capped containers at 4°C.

Medium may be stored for periods of up to two months.

(d) Procedure for preparation of trypan blue solution.

The procedure described is for the preparation of 100 mL of trypan blue solution. It is used in the direct determination of the viable cell counts of the BGM stock cultures. As trypan blue is on the EPA suspect carcinogen list, particular care should be taken in its preparation and use so as to avoid skin contact or inhalation. The wearing of rubber gloves during preparation and use is recommended.

(d.1) Add 0.5 g of trypan blue to 100 mL of dH_2O in a 250 mL flask. Swirl the flask until the trypan blue is completely dissolved.

(d.2) Sterilize the solution by autoclaving at 121°C for 15 minutes and store in a screw-capped container at room temperature.

(e) Procedure for preparation of stock antibiotic solutions.

If not purchased in sterile form, stock antibiotic solutions must be filter-sterilized by the use of 0.22 µm membrane filters. It is important that the recommended antibiotic levels not be exceeded when planting cells as the cultures are particularly sensitive to excessive concentrations at this stage.

Antibiotic stock solutions should be placed in screw-capped containers and stored at -20°C until needed. Once thawed, they may be refrozen; however, repeated freezing and thawing of these stock solutions should be avoided by distributing them in quantities that are sufficient to support a week's cell culture work.

(e.1) Preparation of penicillin-streptomycin stock solution.

The procedure described is for preparation of ten 10 mL aliquots of penicillin-streptomycin stock solution at concentrations of 1,000,000 units of penicillin and 1,000,000 µg of streptomycin per 10 mL unit. The antibiotic concentrations listed in step 6.4.2e.1.1 may not correspond to the concentrations obtained from other lots or from a different source.

(e.1.1) Add appropriate amounts of penicillin G and dihydrostreptomycin sulfate to a 250 mL flask containing 100 mL of dH_2O. Mix the contents of the flasks on magnetic stirrer until the antibiotics are dissolved.

For penicillin supplied at 1435 units per mg, add 7 g of the antibiotic.

For streptomycin supplied at 740 mg per g, add 14 g of the antibiotic.

(e.1.2) Sterilize the antibiotics by filtration through 0.22 µm membrane filters and dispense in 10 mL volumes into screw-capped containers.

(e.2) Preparation of tetracycline stock solution. Add 1.25 g of tetracycline hydrochloride powder and 3.75 g of ascorbic acid to a 125 mL flask containing 50 mL of dH_2O. Mix the contents of the flask on a magnetic stirrer until the antibiotic is dissolved. Sterilize the antibiotic by filtration through a 0.22 µm membrane filter and dispense in 5 mL volumes into screw-capped containers.

(e.3) Preparation of amphotericin B (fungizone) stock solution. Add 0.125 g of amphotericin B to a 50 mL flask containing 25 mL of ddH_2O. Mix the contents of the flask on a magnetic stirrer until the antibiotic is dissolved. Sterilize the antibiotic by filtration through 0.22 µm membrane filter and dispense 2.5 mL volumes into screw-capped containers.

6.5. Procedure for Verifying Sterility of Liquids

There are many techniques available for verifying the sterility of liquids such as cell culture media and medium components. The two techniques described below are standard in many laboratories. The capabilities of these techniques are limited to the detection of microorganisms that grow unaided on the test medium utilized. Viruses, mycoplasma, and microorganisms that possess fastidious growth requirements or that require living host systems will not be detected. Nonetheless, with the exception of a few special contamination problems, the test procedures and microbiological media listed below should prove adequate. Do not add antibiotics to media or medium components until after sterility of the antibiotics, media and medium components has been demonstrated. BGM cell lines should be monitored every six months for mycoplasma contamination according to test kit instructions. Cells that are contaminated should be discarded.

6.5.1 Procedure for Verifying Sterility of Small Volumes of Liquids. Inoculate 5 mL of the material to be tested for sterility into 5 mL of thioglycollate broth. Shake the mixture and incubate at 36.5 ± 1°C. Examine the inoculated broth daily for seven days to determine whether growth of contaminating organisms has occurred.

Vessels that contain thioglycollate medium must be tightly sealed before and after medium is inoculated.

6.5.2 Visual Evaluation of Media for Microbial Contaminants. Incubate media at 36.5 ± 1°C for at least one week prior to use. Visually examine and discard any media that lose clarity.

A clouded condition that develops in the media indicates the occurrence of contaminating organisms.

6.6. Procedures for Preparation and Passage of BGM Cell Cultures

A laminar flow biological safety cabinet should be used to process cell cultures. If a biological safety cabinet is not available, cell cultures should be prepared in controlled facilities used for no other purposes. Viruses or other microorganisms must not be transported, handled, or stored in cell culture transfer facilities.

6.6.1 Vessels and Media for Cell Growth

(a) The BGM cell line grows readily on the inside surfaces of glass or specially treated, tissue culture grade plastic vessels. 16 to 32 oz (or equivalent growth area) flat-sided, glass bottles, 75 or 150 cm^2 plastic cell culture flasks, and 690 cm^2 glass or 850 cm^2 plastic roller bottles are usually used for the maintenance of stock cultures. Flat-sided bottles and flasks that contain cells in a stationary position are incubated with the flat side (cell monolayer side) down. If available, roller bottles and roller apparatus units are preferable to flat-sided bottles and flasks because roller cultures require less medium than flat-sided bottles per unit of cell monolayer surface. Roller apparatus rotation speed should be adjusted to one-half revolution per minute to ensure that cells are constantly bathed in growth medium.

(b) Growth and maintenance media should be prepared on the day they will be needed. Prepare growth medium by supplementing MEM/L-15 medium with 10% serum and antibiotics (100 mL of serum, 1 mL of penicillin-streptomycin stock, 0.5 mL of tetracycline stock and 0.2 mL of fungizone stock per 900 mL of MEM/L-15). Prepare maintenance medium by supplementing MEM/L-15 with antibiotics and 2% or 5% serum (20 or 50 mL of serum, antibiotics as above for growth medium and 70 or 50 mL of dH_2O, respectively).

6.6.2 General Procedure for Cell Passage

Pass stock BGM cell cultures at approximately seven day intervals using growth medium.

(a) Pour spent medium from cell culture vessels, and discard the medium.

To prevent splatter, a gauze-covered beaker may be used to collect spent medium.

Before discarding, autoclave all media that have been in contact with cells or that contain serum.

(b) Add to the cell cultures a volume of warm EDTA-trypsin reagent equal to 40% of the volume of medium replaced.

See Table 2 for the amount of reagents required for commonly used vessel types.

To reduce shock to cells, warm the EDTA-trypsin reagent to 36.5 ± 1°C before placing it on cell monolayers. Dispense the EDTA-trypsin reagent directly onto the cell monolayer.

(c) Allow the EDTA-trypsin reagent to remain in contact with the cells at either room temperature or at 36.5 ± 1°C until cell monolayer can be shaken loose from inner surface of cell culture vessel (about five min).

If necessary, a sterile rubber policeman (or scraper) may be used to physically remove the cell sheet from the bottle. However, this procedure should be used only as a last resort because of the risk of cell culture contamination inherent in such manipulations. The EDTA-trypsin reagent should remain in contact with the cells no longer than necessary as prolonged contact can alter or damage the cells.

(d) Pour the suspended cells into centrifuge tubes or bottles.

To facilitate collection and resuspension of cell pellets, use tubes or bottles with conical bottoms. Centrifuge tubes and bottles used for this purpose must be able to withstand the g-force applied.

(e) Centrifuge cell suspension at 1,000 ×*g* for 10 min to pellet cells. Pour off and discard the supernatant.

Do not exceed this speed as cells may be damaged or destroyed.

TABLE 2. Guide for Preparation of BGM Stock Cultures

Vessel Type	EDTA-Trypsin Volume (mL)[1]	Media Volume (mL)[2]	Total No. Cells to Plate per Vessel
16 oz glass flat bottles[3]	10	25	2.5×10^6
32 oz glass flat bottles	20	50	5.0×10^6
75 cm^2 plastic flat flask	12	30	3.0×10^6
150 cm^2 plastic flat flask	24	60	6.0×10^6
690 cm^2 glass roller bottle	40	100	7.0×10^7
850 cm^2 plastic roller bottle	50	120	8.0×10^7

[1]The volume required to remove cells from vessels.
[2]Serum requirements: growth medium contains 10% serum; maintenance medium contains 2-5% serum. Antibiotic requirements: penicillin-streptomycin stock solution, 1.0 mL/ liter; tetracycline stock solution, 0.5 mL/liter; fungizone stock solution, 0.2 mL/liter.
[3]Size is given in oz only when it is commercially designated in that unit.

(f) Suspend the pelleted cells in growth medium (see section 6.6.1b) and perform a viable count on the cell suspension according to procedures in section 6.7.

Resuspend pelleted cells in sufficient volumes of medium to allow thorough mixing of the cells (to reduce sampling error) and to minimize the significance of the loss of the 0.5 mL of cell suspension required for the cell counting procedure. The quantity of medium used for resuspending pelleted cells varies from 50 to several hundred mL, depending upon the volume of the individual laboratory's need for cell cultures.

(g) Dilute the cell suspension to the appropriate cell concentration with growth medium and dispense into cell culture vessels with either a Cornwall-type syringe or Brewer-type pipetting machine dispenser.

Calculate the dilution factor requirement using the cell count established in section 6.7 and the cell and volume parameters given in Table 2 for stock cultures and in Table 3 for virus assay cultures.

As a general rule, the BGM cell line can be split at a 1:3 ratio. However, a more suitable inoculum is obtained if low passages of the line (passages 100-150) are split at a 1:2 ratio and higher passages (generally above passage 250) are split at a 1:4 ratio. To plant two hundred 25 cm^2 cell culture flasks weekly from a low-level passage of the line would require the preparation of six roller bottles (surface area 690 cm^2 each): two to prepare the six roller bottles and four to prepare the 25 cm^2 flasks.

(h) Except during handling operations, maintain BGM cells at 36.5 ± 1°C in airtight cell culture vessels.

6.6.3 Procedure for Changing Medium on Cultured Cells — Cell monolayers normally become 95 to 100% confluent three to four days after seeding with an appropriate number of cells, and growth medium becomes acidic. Growth medium on confluent stock cultures should then be replaced with maintenance medium containing 2% serum. Maintenance medium with 5% serum should be used when monolayers are not yet 95% to 100% confluent but the medium in which they are immersed has become acidic. The volume of maintenance medium should equal the volume of discarded growth medium.

6.7. Procedure for Performing Viable Cell Counts

With experience a fairly accurate cell concentration can be made based on the volume of packed cells. However, viable cell counts should be performed periodically as a quality control measure.

6.7.1 Add 0.5 mL of cell suspension (or diluted cell suspension) to 0.5 mL of 0.5% trypan blue solution in a test tube.

To obtain an accurate cell count, the optimal total number of cells per hemocytometer section should be between 20 and 50. This range is equivalent to between 6.0 × 10^5 and 1.5 × 10^6 cells per mL of cell suspension. Thus, a dilution of 1:10 (0.5 mL of cells in 4.5 mL of growth medium) is usually required for an accurate count of a cell suspension.

6.7.2 Disperse cells by repeated pipetting.

Avoid introducing air bubbles into the suspension, because air bubbles may interfere with subsequent filling of the hemocytometer chambers.

6.7.3 With a capillary pipette, carefully fill a hemocytometer chamber on one side of a slip-covered hemocytometer slide. Rest the slide on a flat surface for about one min to allow the trypan blue to penetrate the cell membranes of nonviable cells.

Do not under or over fill the chambers.

6.7.4 Under 100X total magnification, count the cells in the four large corner sections and the center section of the hemocytometer chamber.

Include in the count cells lying on the lines marking the top and left margins of the sections, and ignore cells on the lines marking the bottom and right margins. Trypan blue is excluded by living cells. Therefore, to quantify viable cells, count only cells that are clear in color. Do not count cells that are blue.

Table 3. Guide for Preparation of Virus Assay Cell Cultures

Vessel Type	Volume of Medium (mL)[1]	Final Cell Count per Bottle
1 oz glass bottle[2]	4	9.0×10^5
25 cm^2 plastic flask	10	3.5×10^6
6 oz glass bottle	15	5.6×10^6
75 cm^2 plastic flask	30	1.0×10^7
16 mm × 150 mm tubes	2	4.0×10^4

[1]Serum requirements: growth medium contains 10% serum; maintenance medium contains 2-5% serum. Antibiotic requirements: penicillin-streptomycin stock solution, 1.0 mL/liter; tetracycline stock solution, 0.5 mL/liter; fungizone stock solution, 0.2 mL/liter.
[2]Size is given in oz only when it is commercially designated in that unit.

6.7.5 Calculate the average number of viable cells in each mL of cell suspension by totaling the number of viable cells counted in the five sections, multiplying this sum by 4000, and where necessary, multiplying the resulting product by the reciprocal of the dilution.

6.8. Procedure for Preservation of BGM Cell Line

An adequate supply of BGM cells must be available to replace working cultures that are used only periodically or become contaminated or lose virus sensitivity. Cells have been held at -70°C for more than 15 years with a minimum loss in cell viability.

6.8.1 Preparation of Cells for Storage

The procedure described is for the preparation of 100 cell culture vials. Cell concentration per mL must be at least 1 x 10^6.

Base the actual number of vials to be prepared on usage of the line and the anticipated time interval requirement between cell culture start-up and full culture production.

(a) Prepare cell storage medium by adding 10 mL of DMSO to 90 mL of growth medium (see section 6.6.1b). Sterilize cell storage medium by passage through an 0.22 µm sterilizing filter.

Collect sterilized medium in 250 mL flask containing a stir bar.

(b) Harvest BGM cells from cell culture vessels as directed in section 6.6.2. Count the cells according to the procedure in section 6.7 and resuspend them in the cell storage medium at a concentration of 1×10^6 cells per mL.

(c) Place the flask containing suspended cells on a magnetic stirrer and slowly mix for 30 min. Dispense 1 mL volumes of cell suspension into 2 mL vials.

6.8.2 Procedure for Freezing Cells

The freezing procedure requires slow cooling of the cells with the optimum rate of -1°C per min. A slow cooling rate can be achieved using the following method or by using the recently available freezing containers (e.g., Nalge Company Product No. 5100-0001 or equivalent) as recommended by the manufacturers.

(a) Place the vials in a rack and place the rack in refrigerator at 4°C for 30 min, in a -20°C freezer for 30 min, and then in a -70°C freezer overnight. The transfers should be made as rapidly as possible.

To allow for more uniform cooling, wells adjoining each vial should remain empty.

(b) Rapidly transfer vials into boxes or other containers for long-term storage.

To prevent substantial loss of cells during storage, temperature of cells should be kept constant after -70°C has been achieved.

6.8.3 Procedure for Thawing Cells

Cells must be thawed rapidly to decrease loss in cell viability.

(a) Place vials containing frozen cells into a 36°C water bath and agitate vigorously by hand until all ice has melted. Sterilize the outside surface of the vials with 0.5% iodine in 70% ethanol.

(b) Add BGM cells to either 6 oz tissue culture bottles or 25 cm^2 tissue culture flasks containing an appropriate volume of growth medium (see Table 3). Use two vials of cells for 6 oz bottles and one vial for 25 cm^2 flasks.

(c) Incubate BGM cells at 36.5 ± 1°C. After 18 to 24 h replace the growth medium with fresh growth medium and then continue the incubation for an additional five days. Pass and maintain the new cultures as directed in section 6.6.

Appendix I
Test Method for Detecting, Enumerating, and Determining the Viability of *Ascaris* Ova in Sludge

1.0 Scope

1.1 This test method describes the detection, enumeration, and determination of viability of *Ascaris* ova in water, wastewater, sludge, and compost. These pathogenic intestinal helminths occur in domestic animals and humans. The environment may become contaminated through direct deposit of human or animal feces or through sewage and wastewater discharges to receiving waters. Ingestion of water containing infective *Ascaris* ova may cause disease.

1.2 This test method is for wastewater, sludge, and compost. It is the user's responsibility to ensure the validity of this test method for untested matrices.

1.3 This standard does not purport to address all of the safety problems, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use. For specific hazard statements, see section 9.

2.0 Referenced Documents

***2.1 ASTM Standards**:*

- D 1129 Terminology Relating to Water[1]
- D 1193 Specification for Reagent Water[2]
- D 2777 Practice for Determination of Precision and Bias of Applicable Methods of committee D-19 on Water[3]

3.0 Terminology

(Definitions and Descriptions of Terms must be approved by the Definitions Advisor.)

3.1 Definitions - For definitions of terms used in this test method, refer to Terminology D 1129.

3.2 Descriptions of Terms Specific to This Standard:

3.2.1 The normal nematode life cycle consists of the egg, 4 larval stages and an adult. The larvae are similar in appearance to the adults; that is, they are typically worm-like in appearance.

3.2.2 Molting (*ecdysis*) of the outer layer *(cuticle*) takes place after each larval stage. Molting consists of 2 distinct processes, the deposition of the new cuticle and the shedding of the old one or exsheathment. The cuticle appears to be produced continuously, even throughout adult life.

3.2.3 A molted cuticle that still encapsulates a larva is called a *sheath*.

3.2.4 Ascarid egg shells are commonly comprised of layers. The outer tanned, bumpy layer is referred to as the *mammillated* layer and is useful in identifying *Ascaris* eggs. The mammillated layer is sometimes absent. Eggs that do not possess the mammillated layer are referred to as *decorticated* eggs.

3.2.5 A potentially infective *Ascaris* egg contains a third stage larva[4] encased in the sheaths of the first and second larval stages.

4.0 Summary of Test Method

4.1 This method is used to concentrate pathogenic *Ascaris* ova from wastewater, sludge, and compost. Samples are processed by blending with buffered water containing a surfactant. The blend is screened to remove large particulates. The solids in the screened portion are allowed to settle out and the supernatant is decanted. The sediment is subjected to density gradient centrifugation using magnesium sulfate (specific gravity 1.20). This flotation procedure yields a layer likely

Item E 000752

to contain *Ascaris* and some other parasitic ova, if present, in the sample. Small particulates are removed by a second screening on a small mesh size screen.[5] The resulting concentrate is incubated at 26EC until control *Ascaris* eggs are fully embryonated. The concentrate is then microscopically examined for the categories of *Ascaris* ova on a Sedgwick-Rafter counting chamber.

5.0 Significance and Use

5.1 This test method is useful for providing a quantitative indication of the level of *Ascaris* ova contamination of wastewater, sludge, and compost.

5.2 This test method will not identify the species of *Ascaris* detected nor the host of origin.

5.3 This method may be useful in evaluating the effectiveness of treatment.

6.0 Interferences

6.1 Freezing of samples will interfere with the buoyant density of *Ascaris* ova and decrease the recovery of ova.

7.0 Apparatus

7.1 A good light microscope equipped with brightfield, and preferably with phase contrast and/or differential contrast optics including objectives ranging in power from 10X to 45X.

7.2 Sedgwick-Rafter cell.

7.3 Pyrex beakers, 2 L. Coat with organosilane.

7.4 Erlenmeyer flask, 500 mL. Coat with organosilane.

7.4 A centrifuge that can sustain forces of at least 660 X G with the rotors listed below.

7.4.1 A swinging bucket rotor to hold 100 or 250 ml centrifuge glass or plastic conical bottles.

7.4.2 A swinging bucket rotor to hold 15 ml conical glass or plastic centrifuge tubes.

7.5 Tyler sieves.

7.5.1 20 or 50 mesh.

7.5.2 400 mesh, stainless steel, 5 inch in diameter.

7.5.3 A large plastic funnel to support the sieve. Coat with organosilane.

7.6 Teflon spatula.

7.7 Incubator set at 26EC.

7.8 Large test tube rack to accommodate 100 or 250 mL centrifuge bottles.

7.9 Small test tube rack to accommodate 15 mL conical centrifuge tubes.

7.10 Centrifuge bottles, 100 or 250 mL. Coat with organosilane.

7.11 Conical centrifuge tubes, 15 mL. Coat with organosilane.

7.12 Pasteur pipettes. Coat with organosilane.

7.13 Vacuum aspiration apparatus.

7.13.1 Vacuum source.

7.13.2 Vacuum flask, 2 L or larger.

7.13.3 Stopper to fit vacuum flask, fitted with a glass or metal tubing as a connector for 1/4 inch tygon tubing.

7.14 Spray bottles (16 fl oz.) (2).

7.14.1 Label one “Water”.

7.14.2 Label one “1% 7X”.

8.0 Reagents and Materials

8.1 Purity of Reagents — Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society[6]. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

[5]This method is based on a protocol published by Bowman, D.D., M.D. Little, and R.S. Reimers (2003) Precision and accuracy of an assay for detecting *Ascaris* eggs in various biosolid matrices. Water Research **37**(9):2063-2072.

[6]Reagent Chemicals, American Chemical Specifications, American Chemical Society, Washington, D.C. For suggestions on testing of Reagents not listed by the American Chemical Society, see Analar Standards for Laboratory Chemicals, BHD Ltd., Poole, Dorset, U.K. and the United States Pharmacopeia and National Formulary, U.S. Pharmaceutical Convention, Inc. (USPC).

Item E 000753

8.2 Purity of Water — Unless otherwise indicated, references to water shall be understood to mean reagent water conforming to Specification D 1193, Type I.

8.3 Preparation of Reagents — Prepare reagents in accordance with Practice E200.

8.3.1 Phosphate-buffered water (1 L = 34.0 g KH_2PO_4, pH adjusted to 7.2 ± 0.5 with 1 N NaOH).

8.3.2 1% (v/v) 7X ("ICN" laboratory detergent) (1 L = 999 mL phosphate-buffered water, 1 mL 7X "ICN", Adjust pH to 7.2 ± 0.1 with 1N NaOH).

8.3.3 Magnesium sulfate, sp. gr. 1.20. (1 L = 215.2 g $MgSO_4$, check specific gravity with a hydrometer; adjust as necessary to reach 1.20).

8.3.4 Organosilane. For coating glassware. Coat all glassware according to manufacturer's instructions.

8.3.5 Fresh *Ascaris* ova for positive control, purified from *Ascaris* infected pig fecal material.

9.0 Precautions

9.1 When handling *Ascaris* ova and biosolids, personal protective measures must be employed to prevent infection. Prevention of infection in humans is a matter of good personal hygiene. Wear a laboratory coat at all times in the laboratory. In addition, latex or nitrile gloves and splash protection safety glasses should always be worn in the laboratory. Mouth pipetting is strictly forbidden. Contaminated pipettes are never laid down on the bench top but are immediately placed in a pipette discard container which has disinfectant in it. Contaminated equipment is separated as it is used into containers for disposable materials and containers for re-cycling. After these containers which are always autoclave pans, are full, they are autoclaved for 30 minutes at 121EC and 15 pounds/in^2. Contaminated glassware is never washed until after it has been autoclaved. Eating, drinking, and smoking in the laboratory is not permitted. Likewise, refrigerators are not to be used for storing lunches or other items for human consumption. If infective *Ascaris* ova are ingested they may cause disease.

10.0 Sampling

10.1 Collect 1 liter of compost, wastewater, or sludge in accordance with Practice D 1066, Specification D 1192, and Practices D 3370, as applicable.

10.2 Place the sample container(s) on wet ice or around chemical ice and ship back to the laboratory for analysis within 24 hours of collection.

10.3 Store the samples in the laboratory refrigerated at 2 to 5EC. Do not freeze the samples during transport or storage.

11.0 Preparation of Apparatus

11.1 Test the centrifuge with a tachometer to make sure the revolution's per minute correlate with the speed gauge.

11.2 Calibrate the incubator temperature with a NIST traceable thermometer.

11.3 Microscope.

11.3.1 Clean the microscope optics.

11.3.2 Adjust the condenser on the microscope, so Köhler illumination is established.

12.0 Procedure

12.1 The percentage moisture of the sample is determined by analyzing a separate portion of the sample, so the final calculation of ova per gram dry weight can be determined. The concentration of ova in liquid sludge samples may be expressed as ova per unit volume.

12.2 Initial preparation:

12.2.1 Dry or thick samples: Weigh about 300 g (estimated dry weight) and place in about 500 ml water in a beaker and let soak overnight at 4 - 10EC. Transfer to blender and blend at high for one minute. Divide sample into four beakers.

12.2.2 Liquid samples: Measure 1,000 ml or more (estimated to contain at least 50 g dry solids) of liquid sample. Place one half of sample in blender. Add about 200 mL water. Blend at high speed for one minute transfer to a beaker. Repeat for other half of sample.

12.3 Pour the homogenized sample into a 1000 mL tall form beaker and using a wash bottle, thoroughly rinse blender container into beaker. Add 1% 7X to reach 900 ml final volume.

12.4 Allow sample to settle four hours or overnight at 4 - 10EC. Stir occasionally with a wooden applicator, as needed to ensure that material floating on the surface settles. Additional 1% 7X may be added, and the mixture stirred if necessary.

12.5 After settling, vacuum aspirate supernatant to just above the layer of solids. Transfer sediment to blender and add water to 500 ml, blend again for one minute at high speed.

12.6 Transfer to beaker, rinsing blender and add 1% 7X to reach 900 ml. Allow to settle for two hours at 4 - 10EC, vacuum aspirate supernatant to just above the layer of solids.

Item E 000754

12.7 Add 300 ml 1% 7X and stir for five minutes on a magnetic stirrer.

12.8 Strain homogenized sample through a 20 or 50 mesh sieve placed in a funnel over a tall beaker. Wash sample through sieve with a spray of 1% 7X from a spray bottle.

12.9 Add 1% 7X to 900 mL final volume and allow to settle for two hours at 4 - 10EC.

12.10 Vacuum aspirate supernatant to just above layer of solids. Mix sediment and distribute equally to 50 mL graduated conical centrifuge tubes. Thoroughly wash any sediment from beaker into tubes using water from a wash bottle. Bring volume in tubes up to 50 ml with water.

12.11 Centrifuge for 10 minutes at 1000 X G. Vacuum aspirate supernatant from each tube down to just above the level of sediment. (The packed sediment in each tube should not exceed 5 mL. If it exceeds this volume, add water and distribute the sediment evenly among additional tubes, repeat centrifugation, and vacuum aspirate supernatant.)

12.12 Add 10 to 15 mL of $MgSO_4$ solution (specific gravity 1.20) to each tube and mix for 15 to 20 seconds on a vortex mixer. (Use capped tubes to avoid splashing of mixture from the tube.)

12.13 Add additional $MgSO_4$ solution (specific gravity 1.20) to each tube to bring volume to 50 mL. Centrifuge for five to ten minutes at 800 to 1000 X g. DO NOT USE BRAKE.

12.14 Allow the centrifuge to coast to a stop without the brake. Pour the top 25 to 35 mL of supernatant from each tube through a 400 mesh sieve supported in a funnel over a tall beaker.

12.15 Using a water spray bottle, wash excessive flotation fluid and fine particles through sieve.

12.16 Rinse sediment collected on the sieve into a 100 mL beaker by directing the stream of water from the wash bottle onto the upper surface of the sieve.

12.17 After thoroughly washing the sediment from the sieve, transfer the suspension to the required number of 15 mL centrifuge tubes, taking care to rinse the beaker into the tubes. Usually one beaker makes one tube.

12.18 Centrifuge the tubes for three minutes at 800 X G, then discard the supernatant.

12.19 If more than one tube has been used for the sample, transfer the sediment to a single tube, fill with water, and repeat centrifugation.

12.20 Aspirate the supernatant above the solids.

12.21 Resuspend the solids in 4 mL 0.1 N H_2SO_4 and pour into a 20-mL polyethylene scintillation vial or equivalent with loose caps.

12.22 Before incubating the vials, mark the liquid level in each vial with a felt tip pen. Incubate the vials, along with control vials containing *Ascaris* ova mixed with 4 mL 0.1 N H_2SO_4, at 26EC for three to four weeks. Every day or so, check the liquid level in each vial. Add reagent grade water up to the initial liquid level line as needed to compensate for evaporation. After 18 days, suspend, by inversion and sample small aliquots of the control cultures once every 2 - 3 days. When the majority of the control *Ascaris* ova are fully embryonated, samples are ready to be examined.

12.23 Examine the concentrates microscopically using a Sedgwick-Rafter cell to enumerate the detected ova. Classify the ova as either unembryonated, embryonated to the first, second, or third larval stage. In some embryonated *Ascaris* ova the larva may be observed to move. See Figure 1 for examples of various *Ascaris* egg categories.

13.0 Calculation

13.1 Calculate % total solids using the % moisture result:

$$\% \text{ Total solids} = 100\% - \% \text{ moisture}$$

13.2 Calculate catagories of ova/g dry weight in the following manner:

$$\text{Ova/g dry wt} = \frac{(NO) \times (CV) \times (FV)}{(SP) \times (TS)}$$

Where:

NO = no. ova
CV = chamber volume(= 1 mL)
FV = final volume in mL
SP = sample processed in mL or g
TS = % total solids

14.0 Report

14.1 Report the results as the total number of *Ascaris* ova, number of unembryonated *Ascaris* ova, number of 1st, 2nd, or 3rd stage larva; reported as number of *Ascaris* ova and number of various larval *Ascaris* ova per g dry weight.

15.0 Keywords

Ascaris, ova, embryonation, viability assay, helminth.

Item E 000755

Notice

The PEC was consulted in a recent (1998-1999) pilot study by Lyonnaise des Eaux concerning the use of a microscope in making helminth ova counts for different types of sludge. Solids and debris present in the sludge being viewed with the microscope were found to impair ones ability to count. Dilution of raw sludge and digested sludge, however, with phosphate-buffered water prior to analyzing them significantly improved the number of ova that could be counted. Raw sludges were diluted by a factor of 20 and digested sludges by a factor of 5. QA/QC procedures were followed to validate this procedure. The PEC should be consulted for more details.

Appendix J
The Biosolids Composting Process

Introduction

Composting is the biological decomposition of organic matter under controlled aerobic conditions. The objectives of composting are to reduce pathogens to below detectable levels, degrade volatile solids, and produce a usable product. Pathogen reduction is a function of time and temperature. Composted biosolids is one way to meet 40 CFR Part 503 pathogen (and vector attraction) reduction requirements. Composted biosolids can meet either a "Process to Significantly Reduce Pathogens" (PSRP/Class B) or a "Process to Further Reduce Pathogens" (PFRP/Class A) standard, depending upon the operating conditions maintained at the facility. Process and operational considerations must be taken into account when a facility desires to meet the pathogen and vector attraction requirements of 40 CFR 503. The 40 CFR Part 503 regulations require composted biosolids applied to the land to meet specific pollutant limits, site restrictions, management practices, and pathogen and vector attraction reduction processes, depending upon whether they: 1) are applied to agricultural land, forest, a public contact site, or a reclamation site; 2) are sold or given away in a bag or other container; or 3) are applied to a lawn or home garden. Discussions provided here are presented in summary form; it is recommended that the facility seek additional details in developing a compost operation.

Composting Process Description

The addition of a bulking agent to sewage sludge provides optimum conditions for the composting process, which usually lasts 3 to 4 weeks. A bulking agent acts as a source of carbon for the biological process, increases porosity, and reduces the moisture level. The composting process has several phases, including the active phase, the curing phase, and the drying phase.

Active phase. During the active or stabilization phase, the sewage sludge/bulking agent mix is aerated and the sewage sludge is decomposed due to accelerated biological activity. The biological process involved in composting can raise the temperature up to 60°C or more. At these high temperatures, all of the disease-causing pathogens are destroyed. Windrow systems must meet this condition by achieving 55°C for a minimum of 15 consecutive days during which time the windrow is turned five times. The critical requirement is that the material in the core of the compost pile be maintained at the required temperatures (55°C) for the required time (3 days). Therefore, the first phase typically lasts 21 days. Aeration is accomplished in one of two ways: 1) by mechanically turning the mixture so that the sewage sludge is exposed to oxygen in the air; or 2) by using blowers to either force or pull air through the mixture.

Curing phase. After the active phase, the resulting material is cured for an additional 30 days to 180 days. At this time, additional decomposition, stabilization, pathogen destruction, and degassing takes place. Composting is considered complete when the temperature of the compost returns to ambient levels. Depending upon the extent of biodegradation during the active phase and the ultimate application of the finished product, the curing phase may not be carried out as a separate process.

Drying phase. After curing, some operations add another step called the drying phase which can vary from days to months. This stage is necessary if the material is to be screened to either recover the unused bulking agent for recycling or for an additional finished product. If the product is to be marketable, the final compost should be 50% to 60% solids.

There are two main process configurations for the composting process:

Unconfined composting. This process is conducted in long piles (windrows) or in static piles. Operations using unconfined composting methods may provide oxygen to the compost by turning the piles by hand or machine or by using air blowers which may be operated in either a positive (blowing) or negative (suction) mode. For windrows without blower aeration, it is typical to turn the windrow two or three times a week, using a front-end loader. Properly operating aerated static piles do not require turning.

Confined (in-vessel) composting. This process is carried out within an enclosed container, which minimizes odors and process time by providing better control over the process variables. Although in-vessel composting has been effective for small operations, typically these operations are proprietary and therefore will not be described any further in this fact sheet.

Operational Considerations

The key process variables for successful composting are the moisture content and carbon to nitrogen (C:N) ratio of the biosolids/bulking agent mixture, and temperature and aeration of the compost pile. Other process parameters such as volatile solids content, pH, mixing and the materials used in the compost also affect the process.

Bioso/ids/Bu/king Agent Mixture Moisture Content. Moisture control is an important factor for effective composting. Water content must be controlled for effective stabilization, pathogen inactivation, odor control and finished compost quality (Benedict, 1988). The optimum moisture content of the mix is between 40% and 60%. At less than 40% water, the material is too fluid, has reduced porosity and has the potential for producing septic conditions and odors; above 60% solids, the lack of moisture may slow down the rate of decomposition. Since typical dewatered sewage sludge or biosolids are often in the range of 15% to 20% solids for vacuum filtered sewage sludge or biosolids and 20% to 35% solids for belt press or filter pressed sewage sludge or biosolids, the addition of drier materials (bulking agents) is usually essential.

Biosolids/Bulking Agent Mixture Carbon to Nitrogen Ratio. Microorganisms need carbon for growth and nitrogen for protein synthesis. For efficient composting, the carbon to nitrogen (C:N) ratio of the biosolids/bulking agent mixture should be in the range of 25:1 to 35:1

Oxygen /eve/s. For optimum aerobic biological activity, air within the pile should have oxygen levels of between 5% and 15%. Lower levels of oxygen will create odors and reduce the efficiency of the composting. Excessive aeration will cool the pile, slow the composting process, and will not provide the desired pathogen and vector attraction reduction.

Conventional windrows obtain necessary oxygen through the natural draft and ventilation induced from the hot, moist air produced during active composting and from the periodic windrow turning. Where blowers are used for aeration, it is typical to provide at least one blower per pile.

Biosolids/Bulking Agent Mixture Volatile Solids Con tent. The volatile solids content of the biosolids/bulking agent mix should be greater than 50% for successful composting (EPA, 1985). This parameter is an indicator of the energy available for biological activity and therefore compostability.

Bioso/ids/Bu/king Agent Mixture pH. The pH of the biosolids/bulking agent mix should be in the range of 6 to 9 for efficient composting (EPA, 1985). Higher pH mixtures may result if lime stabilized biosolids are used. They can be composted; however, it may take longer for the composting process to achieve the temperatures needed to reduce pathogens.

Biosolids and Bulking Agent Mixing. Uniform mixing is necessary in order to assure that moisture concentration is constant through the pile and that air can flow throughout.

Type of Biosolids. The type of biosolids used may have an effect on the composting process. Composting can be accomplished with unstabilized biosolids, as well as anaerobically and aerobically digested biosolids. Raw sludge has a greater potential to cause odors because they have more energy available and will, therefore, degrade more readily. This may cause the compost pile to achieve higher temperatures faster unless sufficient oxygen is provided and may also cause odors (EPA, 1985).

Material for Bulking Agents. Materials such as wood chips, sawdust and recycled compost are usually added as "bulking agents" or "amendments" to the compost mixture to provide an additional source of carbon and to control the moisture content of the mixture. Other common bulking agents used by facilities around the country include wood waste, leaves, brush, manure, grass, straw, and paper (Goldstein, 1994). Because of their cost, wood chips are often screened out from the matured compost, for reuse. Although sawdust is frequently used for in-vessel composting, coarser materials such as wood chips, wood shavings, and ground-up wood are often preferred because they permit better air penetration and are easier to remove. Recycled compost is often used as a bulking agent in windrows, especially if bulking agents must be purchased. However, its use is limited because the porosity decreases as the recycle ages (EPA, 1989). The amount of biosolids and bulking agent which must be combined to make a successful compost is based on a mass balance process considering the moisture contents, C:N ratio, and volatile solids content.

Compost Pile Size. In general, assuming adequate aeration, the larger the pile the better. A larger pile has less surface area per cubic yard of contents and therefore retains more of the heat that is generated and is less influenced by ambient conditions. In addition, less cover and base material (recycled compost, wood chips, etc.) is needed as well as the overall land requirements for the compost operation. Larger piles tend to retain moisture longer. The surface area to volume ratio has an effect on the temperature of the pile. Assuming other factors are constant (e.g., moisture, composition, aeration), larger piles (with their lower surface area to volume ratio), retain more heat than smaller piles. Ambient temperatures have a significant impact on composting operations (Benedict, 1988).

A typical aerated static pile for a large operation would be triangularly shaped in cross section about 3 meters(m) high by 4.5 to 7.5 m wide (15 to 25 feet) at the base by 12 to 15 m long (39 to 50 feet) (Haug, 1980). One survey study indicates that extended aerated static pile (where piles are formed on the side of older piles) heights were typically 12 to 13 feet high. Minimum depths of base and cover materials (recycled compost, wood chips, etc.) were 12 and 18 inches, respectively (Benedict, 1988).

In windrow composting, the compost mix is stacked in long parallel rows. In cross section, windrows may range from rectangular to trapezoidal to triangular, depending

upon the material and the turning equipment. Atypical trapezoidal windrow might be 1.2 m (4 feet) high by 4.0 m (13 feet) at its base and 1.0 m (3 feet) across the top (Haug, 1980).

Monitoring and Sampling of the Compost Pile

Unless the entire composting mass is subject to the pathogen reduction temperatures, organisms may survive and repopulate the mass once the piles or windrows are cooled. Therefore it is crucial that temperatures be attained throughout the entire pile. For aerated static piles or in-vessel systems using static procedures such as tunnels or silos, temperature monitoring should represent points throughout the pile, including areas which typically are the coolest. In aerated static piles this is usually the toes of the pile (Figure 1). Temperatures should be taken at many locations and at various depths to be assured that the core of the pile maintains the required temperature. Records of the temperature, date, and time should be maintained and reviewed on an ongoing basis. Microbial analysis should at a minimum be taken in a matter to represent the entire compost pile. Operational parameters such as moisture, oxygen as well as the others should be monitored at a frequency necessary to assure that the compost operation is operating within acceptable ranges.

For composting, vector attraction reduction (VAR) is achieved through the degradation of volatile solids. The extent to which the volatile solids are degraded is often referred to as compost stability. Stabilization requires sufficient time for the putrescible organic compounds and for other potential food sources for vectors to decompose. Under this vector attraction reduction option, the Part 503 requires that biosolids be maintained under aerobic conditions for at least 14 days, during which time temperatures are over 40°C (104°F), and the average temperature is over 45°C (113°F) (503.33(b)(5). These criteria are based on studies which have shown that most of the highly putrescible compounds are decomposed during the first 14 days of composting and that significant stability is achieved at mesophilic (<45°C) temperatures.

Recommendations for Specific Technologies

Aerated static pile – Aerated static piles should be covered with an insulation layer of sufficient thickness to ensure that temperatures throughout the pile, including the pile surface, reach 55°C. It is recommended that the insulation layer be at least 1 foot thick. Screened compost is a more effective insulation than unscreened compost or wood chips. Screened compost also provides more odor control than the other two materials.

Air flow rate and the configuration of an aeration system are other factors which affect temperature. Air flow must be sufficient to supply oxygen to the pile, but excessive aeration removes heat and moisture from the composting material. The configuration of an aeration system is also important. Aeration piping too close to pile edges may result in uneven temperatures in the pile and excessive cooling at the pile toes. If holes in the perforated piping are too large or not distributed properly, portions of the pile may receive too much air and be too cool as a result.

Windrows – Compliance with the pathogen reduction requirements for windrows depends on proper windrow size and configuration. If windrows are too small, the high surface area to volume ratio will result in excessive heat loss from the pile sides. Turning must ensure that all material

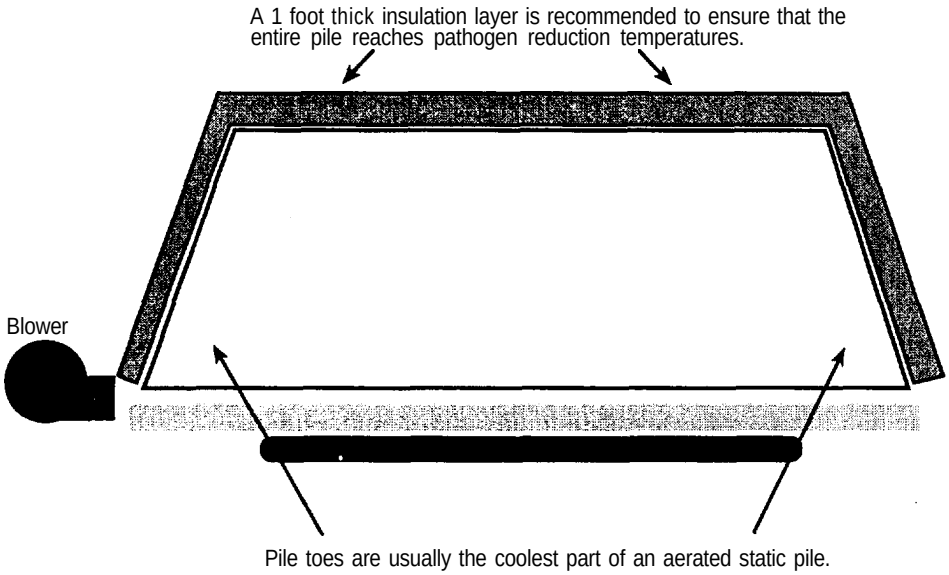

Figure 1a. Aerated static pile.

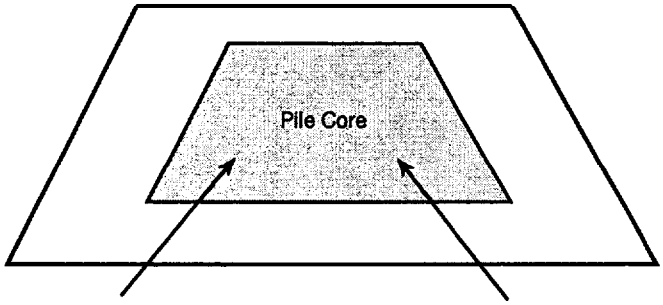

Material turned into the pile core reaches pathogen reduction temperatures. Operations must ensure that all material is turned into the core at some point during composting and that core temperatures rise to 55 degrees after turning.

Figure 1b. Windrow.

in a windrow be introduced into the pile core and raised to pathogen reduction temperatures. This is most easily achieved with a windrow turning machine.

In-Vessel systems- It is difficult to provide guidance for these systems as there are numerous types with varying configurations. Two key factors that apply to all in-vessel systems are aeration and available carbon. As with aerated static piles, the air flow configuration and rate can affect the distribution of aeration to different parts of a composting mass and the temperature profile of a pile. Many in-vessel systems use sawdust as an amendment. This may not provide sufficient energy if the volatile solids in the biosolids are low.

Requirements for Class A/Class B Compost

For class A biosolids, aerated static pile, conventional windrow and in-vessel composting methods must meet the PFRP requirements, including the following temperature/ time requirements:

- Aerated static piles and in-vessel systems must be maintained at a minimum operating temperature of 55°C (131°F) for at least 3 days; and
- Windrow piles must be maintained at a minimum operating temperature of 55°C (131°F) for 15 days or longer. The piles must be turned five times during this period.

For class B biosolids, aerated static pile, conventional windrow and in-vessel composting methods must meet the PSRP requirements, including the following temperature/ time requirements:

- The compost pile must be maintained at a minimum of 40°C for at least five days; and
- During the five-day period, the temperature must rise above 55°C for at least four hours to ensure pathogen destruction. This is usually done near the end of the active composting phase in order to prevent inactivating the organic destroying bacteria.

To meet 40 CFR Part 503 vector attraction reduction requirements using the "aerobic process" alternative, composting operations must ensure that the process lasts for 14 days or longer at a temperature greater than 40°C. In addition, the average temperature must be higher than *45°C.*

NATIONAL SEWAGE SLUDGE SURVEY
SAMPLING PROCEDURES AND PROTOCOLS

1.0 PROJECT DESCRIPTION

This document presents the sampling procedures and protocols for the National Sewage Sludge Survey.

The objective of this sampling project is to visit and collect samples of sewage sludge from a variety of Publicly Owned Treatment Works (POTWs) in an effort to identify the presence and level of toxic pollutants contained in municipal sewage sludge (hereinafter referred to as sludge). After collection and icing, samples will be shipped to laboratories for preservation and analysis. Laboratory tests will be performed for: 1) those analytes listed in The 1987 Industrial and Technology Division List Of Analytes, and 2) the following non-conventional pollutants:

Fluoride
TKN
Nitrate
Nitrite
Phosphorous
Percent solids
Cyanide

2.0 SAMPLE METHOD SELECTION

Representative sampling may be performed using either grab samples or long-term composite samples.

Grab sampling consists of collecting a single sample for each different and segregated sludge product produced during a POTW's normal daily operations. A grab sample is a sample collected over a short period (usually less than 15 minutes) during the daily operation of a POTW. This is the quickest and least expensive way of collecting reliable sludge samples.

Composite sampling consists of consecutively collecting samples (weekly, monthly, etc.) over a period of time and requires considerably more man-hours to accomplish. Long-term sampling incorporates the effects of seasonal climatic changes, POTW operating procedures, long-term industrial production cycles, and the number and type of POTW collection system connections (domestic/industrial) on the sludge pollutant concentrations. A long-term sampling program is of more benefit in describing the changes associated with POTW sludge production over extended periods.

The quickest and most cost effective, yet representative, sample collection method for the purpose of this study is short-term sampling. Grab samples are adequate to characterize the quality of sludges prior to final disposal, because the long sludge detention times found at POTWs reduces the variability of the sludge characteristics. Processes which produce sludge and/or add to a POTW's sludge detention time include:

A. Primary Clarification: Located at the head of the treatment plant, easily settleable and floatable materials are removed from the wastewater. Sludge mixing is minimal until the primary sludge is pumped to digesters and thickeners for mixing with other process sludges.

B. Activated Sludge/Secondary Clarification: The constant recycling of biomass within the process generates sludges with process ages (sludge detention times) of 5 to 30 days. Sludge detention times vary dependent upon process modifications.

C. Other Biological Treatment Processes: Trickling filters, rotating biological contactors and other fixed media systems have intermittent sloughing off of biomass which cause sludge to vary in quality and quantity.

D. Chemical Precipitation/Coagulation: After secondary treatment (where 80% to 90% of the pollutants have been removed), chemicals such as aluminum hydroxide, ferric chloride, lime and polymers are added to further treat the wastewater. Some sludge is recycled and detention times reach 1 to 2 days. These sludges are frequently difficult to dewater and are normally mixed with digested or undigested biological sludges prior to further processing.

E. Sludge Holding/Gravity Thickeners/Elutriation Tanks: Due to process constraints such as septicity, sludge detention time is normally no more than 1 to 2 days.

F. Aerobic/Anaerobic Digesters: Detention times of 20 to 30 days normally are found in these sludge stabilization processes.

G. Miscellaneous Stabilization Processes: Additional sludge stabilization processes, such as lime stabilization, chlorine oxidation, heat treatment, and wet air oxidation, can drastically change a sludge's characteristics but have a very small effect on its detention time.

A POTW may use one or more of the above processes to treat wastewater and to condition sludge before dewatering, composting, and final use/disposal. The combined detention times: 1)

disperse and dilute any slugs or otherwise non-representative concentrations of pollutants, and 2) produce a consistently homogenous mixture of sludge. For this reason, a grab sample could adequately represent a 20- or 30-day composite sample.

A short-term effect on sludge quality may be felt during dewatering. Equipment used in the process (belt presses, centrifuges, vacuum filters) does not generate a product of constant dryness. The percent solids (or percent moisture) may vary, depending on chemical feed rates, septicity of incoming liquid sludge, and differences among machines. As the percent solids of the final product varies so will the amount of water soluble pollutants. This can be avoided to some degree by sampling only during normal operating hours (i.e., never during a dewatering facilities start-up mode).

Under these controlled sampling circumstances, short-term sampling will provide representative samples of sewage sludges.

3.0 SAMPLE COLLECTION

This section provides the rationale for selecting sampling locations and describes the protocols to be used for sample collection and handling.

3.1 Sample Point Identification

3.1.1 Sample Type Classification

All samples to be collected will be grab samples of the final sludge product or products produced by the POTW. The final sludge product will be defined as sewage sludge after all conditioning, dewatering, etc., but before disposal (i.e., before land application, incineration, landfill, distribution and marketing, permanent lagooning or ocean disposal). In cases where a sewage treatment plant's sludge is transported to another facility for further processing, the sample will be collected at the facility of origin, before transfer.

Individual samples will be collected for each distinct type of sludge segregated and disposed of by the POTW. Individual sludge types may be classified in two categories: liquid and solid. Liquid sludge is defined as any sludge which has the capacity to flow and is conveyed via pump. Solid sludge is defined as any sludge which does not meet the liquid sludge definition.

Liquid and solid subcategories may evolve when sludges produced during various plant processes are segregated, treated, and disposed of individually, as opposed to being blended before treatment and disposal. Each of these final sludge products will be considered as a different and individual sample. Therefore, a POTW may have a variety of final sludge products, liquid and/or solid, combined or individual. Each type will require an

individual grab sample. However, grab samples will be collected and combined when similar dewatering devices are used for the same type of sludge.

The following is a description of an imaginary POTW to demonstrate the classification of various final sludge types.

EXAMPLE

POTW "X" (refer to "Generic" POTW flow diagram, Figure 1) consists of primary clarification, activated sludge and secondary clarification, chemical treatment/precipitation, aerobic digestion, sludge thickening and dewatering through the use of one centrifuge, two belt presses and a drying bed.

Primary clarifier sludge and secondary clarifier sludge (i.e., waste activated sludge) are sent to the aerobic digester for stabilization. Sludge from the aerobic digester is then dewatered using a centrifuge, belt press #1, and the drying bed. The solid sludge is landfilled.

Sludge produced in the chemical treatment/precipitation unit is mixed with additional aerobically digested sludge in the thickener. Half of this mixture is dewatered using belt press #2 and landfilled. The other half is hauled away as a liquid and applied to farmland.

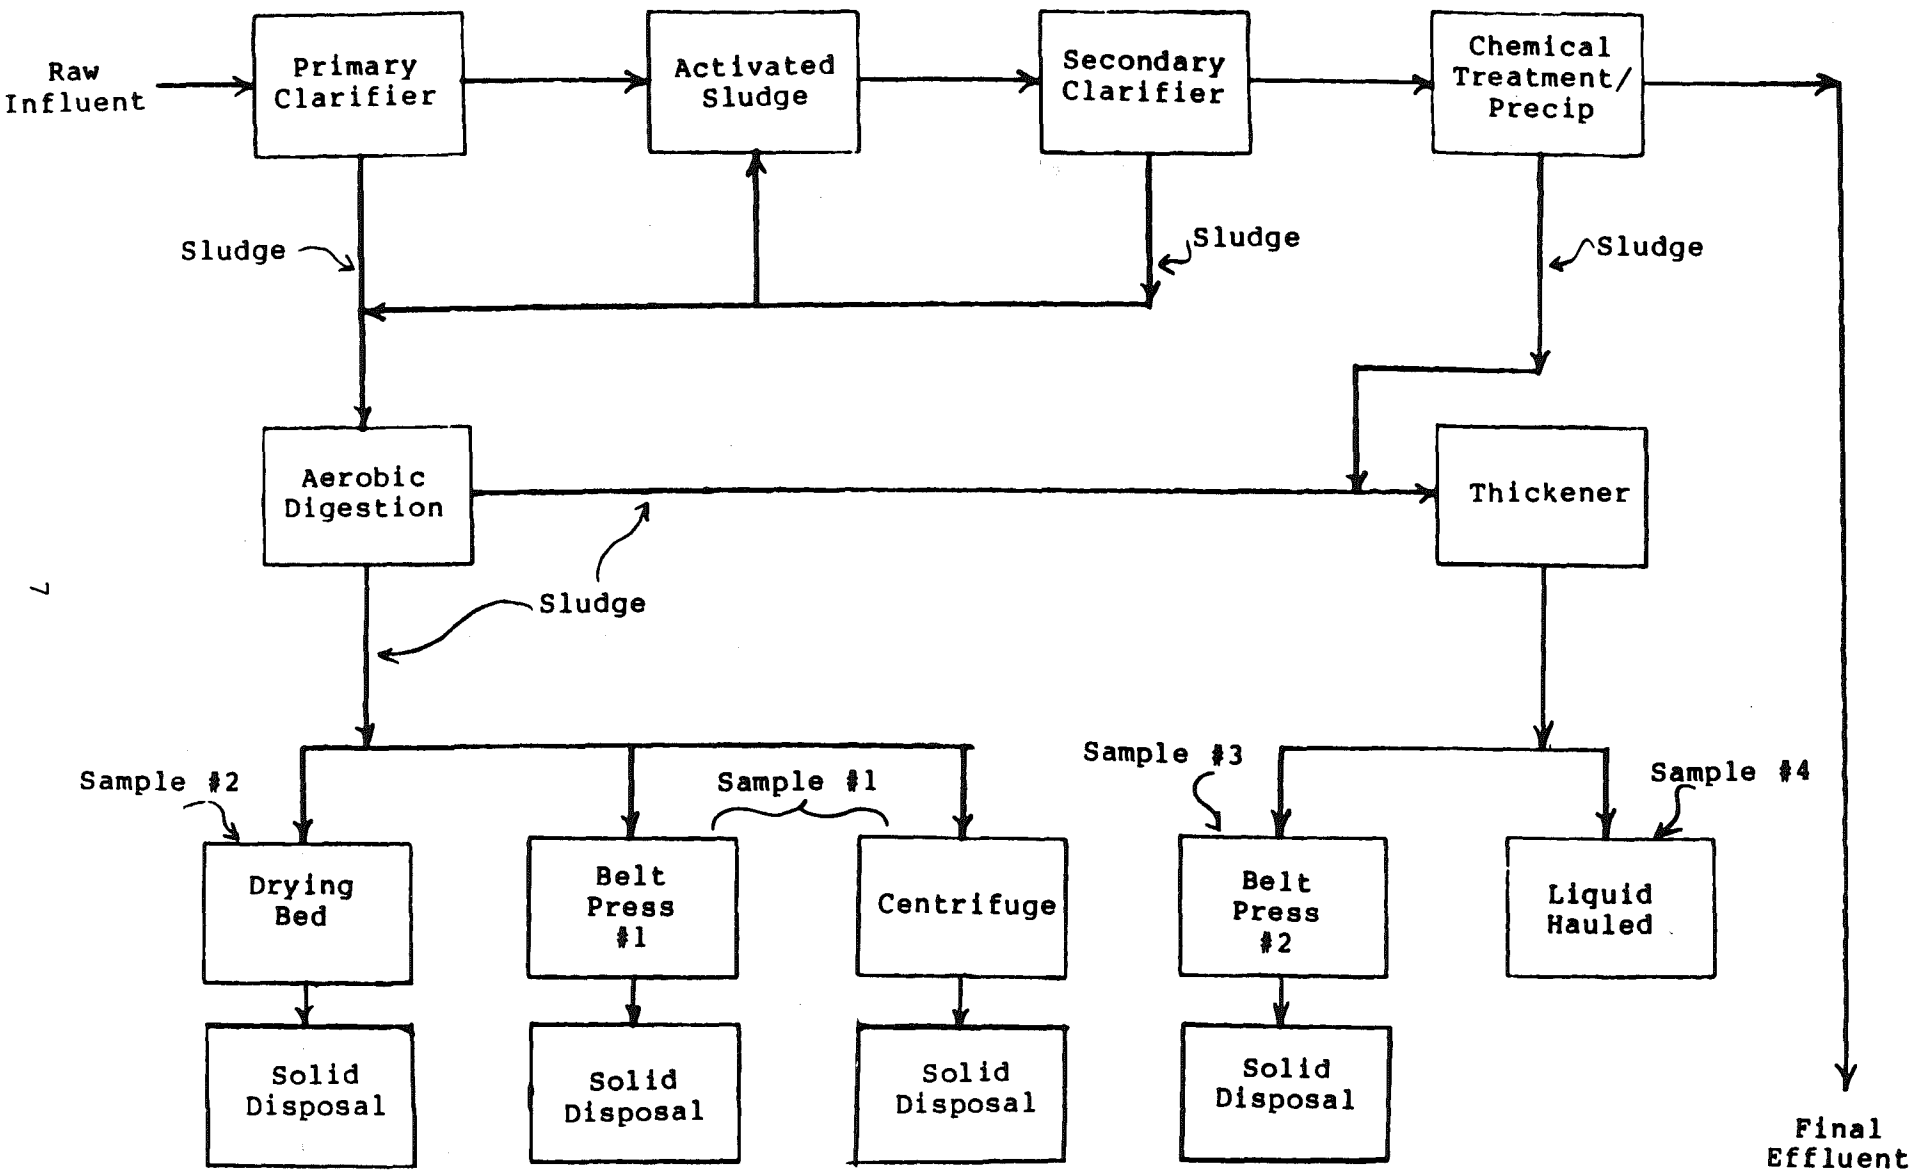

Figure 1. POTW "Generic" Flow Diagram

The individual sludge samples that should be collected at this imaginary POTW are as follows:

Sample #1 - Aerobically digested sludge from the centrifuge and belt press #1: Both the centrifuge and belt press #1 are dewatering the same type of sludge. A grab sample would be collected from each machine and combined to form a single representative sample.

Sample #2 - Aerobically digested sludge from the drying bed: This is a separate sample. Aerobically digested sludge in Sample #2 is being dewatered in a radically different way than in Sample #1. Drying beds reduce the moisture content of a sludge much more than centrifuges and belt presses. Also chemical and physical changes in the sludge occur due to the long holding time and exposure to elements while on a drying bed. Grab samples of different areas of the drying bed (as described in Section 3.2.1.C) would be collected and combined to form a representative sample.

Sample #3 - The chemical and aerobically digested sludge mixture dewatered on belt press #2: This is a different sludge type from Samples #1 and #2. A separate grab sample would be collected.

Sample #4 - The chemical and aerobically digested sludge mixture hauled away as a liquid: This is the same sludge as in Sample #3, except in liquid form. The liquid is treated as a different sludge type, and a grab sample is collected.

Sampling points for the above samples are shown in Figure 1.

3.1.2 Sample Collection Point Selection

The following procedures should be followed to select the appropriate collection point necessary for representative grab samples once each individual sludge type has been identified. Appendix A, taken from the U.S. EPA POTW Sludge Sampling and Analysis Guidance Document, contains additional information on commonly used sludge sampling points.

Solid Sludge Collection Point

Samples of solid sludge should be collected directly from the final sludge treatment processes. These processes include, but are not limited to, belt filter press (continuous), plate and frame sludge press (batch), centrifuge, vacuum filter, compost pile and drying beds (sand beds, cement pads, drying lagoons, vacuum assisted drying beds).

A. Belt Filter Press/Centrifuge/Vacuum Filter: Each process dewaters sludge continuously. The sample should be collected from the sludge discharge chute.

B. Sludge Press (plate and frame): This is a batch process and discharges sludge cake intermittently. Sludge is dewatered in the press until plates are full. The unit is then opened and sludge cake is dropped into a bin. Samples should be collected directly from the storage bin.

C. Drying Beds (drying lagoons, cement pads, sand beds, vacuum assisted drying beds): Drying beds are also a batch process. Each bed should be divided into quarters. One grab sample should be collected from the center of each quarter and all grabs combined from all beds to form a complete sample. Sludge should not be sampled until ready for removal from beds. The criteria for removal vary from facility to facility. Sludge should be collected from beds which are ready for clearing, as deemed by the facility's manager. Drying beds are normally encountered at smaller POTWs, where sludge production is variable. Therefore, sample scheduling must be coordinated to take place when sludge is available and ready for removal.

D. Compost Piles: This is an additional conditioning process in which the dewatered sludge (from one of the previous processes) is mixed with a bulking agent such as wood chips, aerated in large piles, and allowed to stabilize. This process takes a few weeks. The sample should be collected from piles which have completed composting and are ready for disposal. A representative sample scheme should be determined through discussions with the compost facility manager.

Liquid Sludge Collection Point

Liquid sludge normally is transported off the POTW site in tanker trucks. The sampling point should be as close to the truck loading point as possible. The ideal liquid sludge sample point would be at the end of the hose or pipe that is used to fill the tanker truck. If this is inaccessible, optional sampling points such as taps on sludge process piping should be used. When locating a sampling point within the process piping, the

following procedures should be followed to ensure that representative samples are obtained.

A. In sludge treatment process trains the most representative sample typically is obtained from a tap on the discharge side of sludge pumps. Flow at this point in the system is turbulent and the sludge is well mixed.

B. If a sample is drawn from a tap on a pipe containing sludge that is distant from the sludge pump, the average flow velocity of the sludge in the pipe should be determined. Average velocities of less than 2 feet per second are likely to result in solids separation and settling, with an attendant effect on sample solids content, depending on the location of the tap (top, side or bottom of the pipe). Given a choice, a tap on the side of the pipe is preferable.

3.2 Sample Collection Procedures

The following general steps are to be taken by the sampling team for proper sample collection:

A. The sampling team leader, through consultation with the POTW Manager, should establish the number of sludge types leaving the plant for final disposal and the sample points for each sludge type as designated in Section 3.1. The percent solids of each type also must be established. Sludges with solid contents more than 2 percent should use the sample volumes shown in Table 1; sludges with solid contents less than 2 percent should use the sample volumes listed in Table 2. This information, along with contacts, phone numbers, facility address, directions to facility, and necessary safety equipment required (hard hat, safety shoes, etc.), should be written up in a pre-sampling report. One copy each should go to the project manager, sample team, and file.

   If unexpected difficulties are encountered on site when locating sludge sample points, or if sampling is impossible, the project manager should be notified immediately and sampling plan modifications made.

B. To remove any sample contamination potential, all sampling equipment is to be made of polyethylene or polypropylene, used only once, and discarded.

TABLE 2
SAMPLE CONTAINER DESCRIPTIONS

Sludge Samples Containing <2% Solids

SAMPLE TYPE	VOLUME REQUIRED	TYPE OF CONTAINER
GC/MS for:		
Semi-volatile Org	4 each 500ml	G
Volatile Organics	4 each 4oz	G
GC/MS for:		
Dioxin/Furan	500ml	G
GC for:		
Pesticides/PCBs	4 each 500ml	G
Herbicides	2 each 500ml	G
ICP & AA for:		
27 IFB metals	500ml	P
Non-conventionals:	4 each 500ml	P
Fluoride		
TKN		
Nitrate		
Nitrite		
Phosphorous		
% Solids		
Cyanide		

G - glass
P - polyethylene

Polyethylene gloves also must be worn to prevent sample contamination and to provide for worker safety.

C. Prior to sample collection, each sample container should be labeled with a sample number. A set of sample numbers (all identical) should be used for one sample point and discarded. Each sample number label should have the sample type written on it (i.e., metals, classicals, dioxin/furan, extractables, VOA unpreserved, VOA unpreserved duplicate, VOA trip blank, VOA trip blank duplicate, pesticides/PCB's or herbicides). Some labels are preprinted; others will require the sample type to be written in. After the sample number is applied to the container, a piece of wide clear type should be applied to protect the label from dirt and liquids. If a label is mis-marked, it should be replaced; do not write over a mistake. Dioxin/furan samples should be labeled on both the inside glass sample container and outside plastic secondary container. Only one metals sample is collected and the label used may say ICP or AA.

D. At each sampling point, the required amount of sample should be collected, following procedures as described in this document.

E. Fifteen percent of the samples are to have duplicates collected. Duplicate samples are to be identified with a new sample number. There should be no written reference to the duplication of samples on traffic reports.

F. Organic volatile trip blanks should be used to determine the extent of contamination, if any, arising from sample container handling and field conditions encountered during the POTW visits. Trip blanks are organic-free samples of reagent grade water prepared by a designated laboratory before the sampling trip. These blanks are to be handled and shipped with the collected sludge samples to the laboratory for analysis. These blanks should not be opened until arrival at the laboratory. One set of two trip blanks will be used at 15 percent of the sites.

G. All sample containers (including trip blanks) should be sealed by applying a piece of clear wide tape around the top, thus preventing the lid from popping off or unscrewing. Each glass sample container should be wrapped with a piece of bubble wrap. The bubble wrap should be secured with a piece of shipping tape.

H. After all containers have been taped and wrapped, they should be packed into their respective coolers. All material (except one layer of bubble wrap on the bottom of the cooler) should be removed from the cooler and the cooler lined with a large trash bag. Each sample container then should be packed into the cooler, and ice should be applied to the samples. All ice should be packed in zip-lock bags to help prevent any leaking during shipment. With sample containers and ice inside the cooler, the trash bag should be tied closed (also to help prevent leaks). More bubble wrap should be added to fill the remaining space in the cooler, the pink and gold copies of trip report enclosed on top, and the cooler closed and wrapped with shipping tape.

I. Refer to Appendix B for instructions on completing traffic reports and other pertinent information about the Sample Control Center.

J. Each cooler should be shipped via overnight delivery service. The Sample Control Center should be called to provide them with sample collection information.

K. The sampling team also will record site information. These data will be recorded on a preprinted log sheet and will include at least: date, POTW name and address, name of POTW contact, sample identification number and sample point description, basic descriptions of POTW sludge treatment processes and final sludge disposal method(s).

3.2.1 Solid Sludge Sample Collection

At the sample point(s), a sample of solid sludge will be collected using a polyethylene pail and polypropylene scoop.

A. Belt Press/Centrifuge/Vacuum Filter: These sludge dewatering processes are continuous. When one or a combination of these dewatering devices are encountered and used to dewater the same sludge type, then only one sample is collected.

1. If just one dewatering unit is present, a sufficient amount of solid sludge is collected (refer to sample amounts in Table 1) in the polyethylene pail directly from the sludge discharge chute. The sample is thoroughly mixed with the polypropylene scoop and/or coring device (Figure 2). The sludge should be transferred to

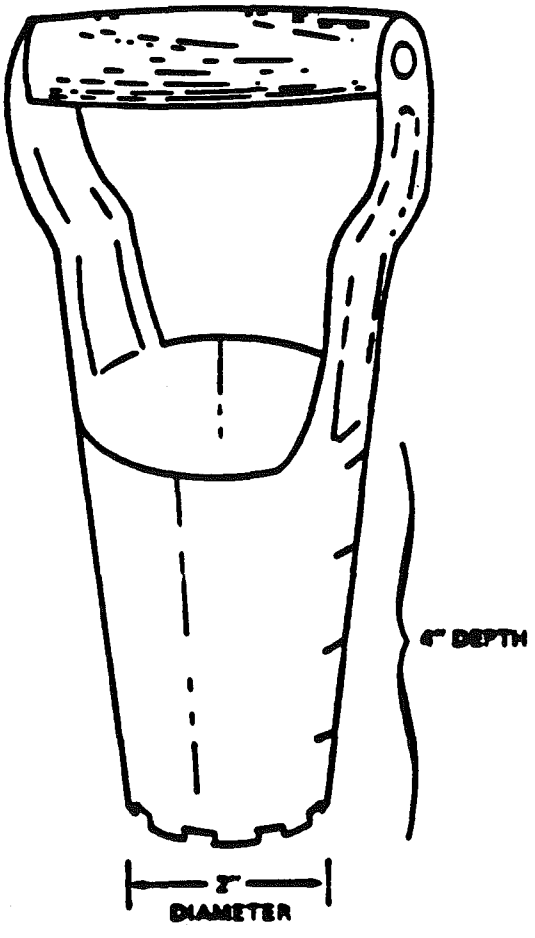

FIGURE 2. Coring Device

*These devices do very well at mixing and reducing particle size of samples, as well as the actual sample collection.

the required sample containers by means of the polypropylene scoop as described in Section 3.2.2.

2. If two or more dewatering units (any combination) machines are present (dewatering the same sludge type), equal amounts of solid sludge are to be collected from each discharge point and combined in the polyethylene pail, the sample thoroughly mixed with the polypropylene scoop and/or coring device, and the sludge transferred to the required sample containers by means of the polypropylene scoop as described in Section 3.2.2.

B. Sludge Press (plate and frame): To collect a representative sample, at least four points within the sludge bin must be selected. An equal amount of sample is collected (refer to Table 1) from each point and combined in the polyethylene pail. The sample is thoroughly mixed with the polypropylene scoop and/or coring device, and the sludge is transferred to the required sample containers by means of the polypropylene scoop as described in Section 3.2.2.

C. Drying Beds: The sludge must be sufficiently dry before sampling may take place. The sludge dryness will vary based on the particular POTW's circumstances. The sampling visit should be scheduled to coincide with a POTW's decision that a drying bed is ready for cleaning. Sludge should be collected from only those beds deemed ready for cleaning. The POTW Manager's assistance should be used for scheduling.

1. To collect the sample, the bed is divided into quarters and equal amounts of sample are grabbed from the center of each quarter using a coring device. Enough sample should be collected to fill the sample containers (refer to Table 1). The sample should include the entire depth of sludge on the bed. Care must be taken not to include large amounts of the drying bed sand when the sample is collected. A small amount of sand is allowable though, as this would be representative of the fact that during normal sludge removal, small amounts of sand are usually taken. The four grabs should be combined in the polyethylene pail, the sample thoroughly mixed with the polypropylene scoop and/or coring device, and the sludge transferred to the required sample containers by means of the polypropylene scoop as described in Section 3.2.2.

2. If more than one drying bed is used to dewater the same sludge type, the above sampling technique should be used on each bed. All the samples should be combined in the polyethylene pail, the sample thoroughly mixed with the polypropylene scoop and/or coring device, and the sludge transferred to the required sample containers by means of the polypropylene scoop as described in Section 3.2.2.

D. Compost Pile: A grab sample should be collected from a compost pile or piles that are ready for disposal using the polyethylene pail, scoop and corer (refer to Table 1 for total amount of sample needed). The compost pile should be divided into equal sections. Using the coring device, equal amounts of sample should be collected from each section to form a complete grab sample. The sample should be thoroughly mixed with the polypropylene scoop and/or coring device and the sludge transferred to the required sample containers by means of the polypropylene scoop as described in Section 3.2.2.

3.3.2 Solid Sludge Handling

The following describes the procedures for the handling of solid sludge samples and filling of sample containers. Refer to Table 1 for sample volumes.

A. Organic Volatiles/Semi-volatiles: The sludge should be thoroughly mixed in the sample pail, using the polypropylene scoop, and the labeled sample container filled. The sludge should be carefully packed into the container so as to avoid air spaces. Covering one's hand in a clean polyethylene glove and packing the sludge with the fingers seems to be the easiest method. The labeled container should be filled to overflowing, and the lid screwed on, wrapped, and sealed with clear tape.

B. Dioxin/Furan: The sludge should be thoroughly mixed in the sample pail, using the polypropylene scoop, and the labeled sample containers filled to four-fifths full. This is to enable expansion of the samples when they are stored at <0°C. Storing at <0°C preserves the samples and prevents biological activity that may change the chemical characteristics of the sludge. Air

spaces are of no concern. The lid should be wrapped and sealed with clear tape. These samples are to be frozen to facilitate a longer holding time before analysis.

C. Pesticides/PCBs/Herbicides, Metals and Non-Conventionals: The sludge should be thoroughly mixed in the sample pail, using the polypropylene scoop, and each labeled sample container filled to within 1/2 inch of top. This provides room for expansion should there be any gas production due to biological activity. Air spaces within the sludge are of no concern. The lid should be wrapped and sealed with clear tape.

3.2.3 Liquid Sludge Sample Collection

At the sample point, liquid sludge should be collected directly into the 14-quart polyethylene pail. Enough sample should be collected to fill the sample container (refer to the appropriate table, Table 1 or Table 2). When drawing the liquid sludge from:

A. Completely Mixed Tank:

1. The POTW operator should start and run the pump for 5 minutes to clear the line of stagnant sludge.

2. Sludge must be allowed to flow for several seconds from the tap (or sample outlet) prior to sampling in order to flush out stagnant sludge and solids that may have accumulated in the tap.

3. The polyethylene pail should then be filled.

B. Unmixed Tank:

1. An unmixed tank will have a sludge layer and supernatant layer; the sludge pump must draw from the sludge layer.

2. The POTW operator should start and run pump for 5 minutes to clear the line of stagnant sludge.

3. Sludge must be allowed to flow for several seconds from the tap (or sample outlet) prior to sampling in order to flush out stagnant sludge and solids that may have accumulated in the tap.

4. The polyethylene pail should then be filled.

Before transferring liquid sludge into sample containers (see Section 3.2.4), the liquid sludge should be manually agitated in the pail with a polyethylene ladle until thoroughly mixed.

3.2.4 Liquid Sludge Handling

The following describes the procedures for the handling of liquid sludge samples and filling of sample containers. Refer to Table 1 or Table 2 for sample volumes (this will be based on the expected percent solids of the sample).

A. Organic Volatiles/Semi-volatiles: The sludge should be thoroughly mixed in the sample pail, using the polyethylene ladle, and each labeled sample container filled. The sludge should be carefully side-poured into the container so as to avoid entrapping air within the sample. The container should be filled to overflowing and the lid screwed down. The sample should be checked for air bubbles. To do this, the container is turned up-side-down and the lid tapped. If air bubbles rise up, the container should be opened and filled with additional sample. When there are no further air bubbles, the container should be wrapped and the lid sealed with clear tape.

B. Dioxin/Furan: The sludge should be thoroughly mixed in the polyethylene pail, using the polyethylene ladle, and each labeled sample container filled to four-fifths full; this allows for sample expansion at <0°C. Storing at <0°C will preserve the samples and prevent any biological activity. Air spaces in the sample container are of no concern. The lid should be wrapped and sealed with clear tape. These samples are to be frozen to facilitate a longer holding time before analysis.

C. Pesticides/PCBs/Herbicides, Metals and Non-Conventionals: The sludge should be thoroughly mixed in the polyethylene pail, using the polyethylene ladle, and each sample container filled to within 1/2 inch of the top. This will provide room for expansion should there be any gas production due to biological activity. Air spaces in the sample containers are of no concern. The lid should be wrapped and sealed with clear tape.

4.0 SAMPLE HANDLING AND CUSTODY

This section describes the procedures for sample handling and shipment.

4.1 Sample Handling

Except for mixing of samples in the sample pail, no modifications to the structure or content (removal of plastics, paper, etc.) of the samples will be performed. Sample transfer will be kept to a minimum. The sludge will be placed in polyethylene or glass sample containers which have been analyzed for quality control by the supplier and which are certified to meet U.S. EPA cleanliness specifications.

4.2 Sample Preservation

Once a sample is collected, steps will be taken to preserve the chemical and physical integrity of the sample during transport and storage prior to analysis. All samples will be immediately cooled to a temperature of 4°C or less using regular (wet) ice (which has been purchased and sealed in zip-lock bags prior to the sampling visit) and shipped promptly to the designated

laboratories. Upon arrival at the laboratories, samples will be preserved further or analysis begun as appropriate within 48 hours of the sample collection.

4.3 Sample Shipment

All samples will be shipped from the field on the day of collection using an overnight commercial delivery service. If circumstances prohibit this, samples will be kept on ice and shipped in the most expedient method available.

The shipment box will be of sturdy construction and insulated to provide the proper environment for preserving the samples at <4°C (in this case a regular, 28-quart cooler). Each sample container will be sealed with clear tape to prevent lid removal or leakage. All glass sample containers will be enclosed in bubble wrap. All sample containers will be securely packed in the shipment box with additional bubble wrap. On the outside of the shipment container the following should be placed: 1) a shipping label with the complete address of the receiving laboratory including the responsible laboratory person receiving the samples, 2) a designated box number to indicate to the receiver exactly how many sample boxes are included in the shipment, and 3) "Fragile" and "This End-Up" labels.

4.4 Field Custody Procedures

Each sample container will have a label attached (Figure 3) and covered with clear plastic tape to prevent solvent attack. Shipment record forms will be written for each group of samples shipped to a particular laboratory. These forms will be the standard Sample Control Center Organics Traffic Report, Metals Traffic Report, and (generic) Sample Traffic Report shown in Figures 4, 5 and 6. The pink and gold copies of each form will accompany sample shipment to the laboratory. The yellow copy of each form will remain in the custody of the sample team. The white copy will be delivered directly to the Sample Control Center. Additional details are provided in Appendix B.

5.0 SAMPLING EQUIPMENT

This section lists the sampling supplies and equipment to be used by the sampling team while in the field. Two sets of clean equipment will be saved for an equipment blank analysis. The study will consist of soaking each piece of equipment for 72 hours in laboratory water and analyzing the water for contaminants which may have leached from the sample equipment.

5.1 Sampling Equipment

-Sample kit (to be prepared prior to sampling visits)

Sampling kits will be prefabricated and ready for use before sampling begins. The kits will contain:

-High impact plastic coolers with lids

-Sample containers (see Table 1 and/or Table 2)

5.0 SAMPLING EQUIPMENT

This section lists the sampling supplies and equipment to used by the sampling team in the field to collect samples.

5.1 Sampling Equipment

-Sample kit (to be prepared prior to sampling visits)

-Disposable 14 quart polyethylene pails

-Disposable polyethylene gloves

-Disposable polypropylene scoops

-Disposable stainless steel corers

-Disposable polyethylene ladles

5.2 Miscellaneous

-Clear tape (to seal sample containers)

-Packing tape

-Writing tools

-Clear plastic zip-lock bags

-Shipping materials

-Shipping instructions and appropriate shipping forms

-Trash bags

6.0 SAMPLING KITS

Sampling kits will be prefabricated and ready for use before sampling begins. The kits will contain;

-High impact plastic coolers with lids

-sample containers (refer to Table I)

all sample containers will be certified to meet USEPA cleanliness specifications and will have been quality control analyzed by the supplier

-packing materials (bubble wrap, peanuts, etc.)

APPENDIX A

COMMONLY USED SEWAGE SLUDGE SAMPLING POINTS

Sludge Type	Sampling Point
Primary Sludge -	Most frequently sampled from taps on the discharge side of positive displacement pumps. Difficult to sample from wells or pits due to solids separation.
Activated Sludge -	Sampled from taps on lines or from open channel flows. Open channel flow can be considered an acceptable sample point if the flow is well mixed.
Trickling Filter Humus -	Sampled at taps on discharge lines from pumps or from wells, pits or channels. Care should be taken to assure adequate mixing, since humus has a greater tendency for solids separation than activated sludge.
Anaerobically Digested Sludge -	Typically sampled from taps on the discharge side of positive displacement pumps.
Aerobically Digested Sludge -	Frequently sampled from taps on discharge lines from pumps. In some cases, particularly where batch digestion is used, sludge may be sampled directly from the digester. Two cautions are in order concerning this practice: (1) If aerated during sampling, significant air will be entrained in the sample. Depending on parameters to be analyzed, this may affect sample integrity. (2) If aeration is shut off, solids separation will occur rapidly in well digested sludge, affecting sample representativeness.
Thickened Sludges -	Typically sampled from taps on the discharge side of positive displacement pumps.
Heat Treatment Sludge -	Generally sampled from taps on the discharge side of positive displacement pumps after decanting. Particular care should be taken when sampling heat treatment sludge due to: (1) High tendency for solids separation, and (2) High temperature of sample (frequently 60°C+ as sampled) can cause problems with certain sample containers due to cooling and subsequent contraction of entrained gases.
Dewatered Sludges (Cake) -	Generally sampled from the conveyors on which dewatered sludge is collected. If sampled from bulk containers, sample should be taken from several locations within the sludge mass.

APPENDIX B

USEPA INDUSTRIAL TECHNOLOGY DIVISION
SAMPLE CONTROL CENTER
SAMPLE SCHEDULING AND SHIPMENT INSTRUCTIONS

Sample Scheduling

To schedule a sampling site, an authorized requestor should call the Sample Control Center (SCC) with the following information:

- Name and affiliation and the telephone number of the individual requesting the analysis
- The analyses requested
- Facility name and location
- Industrial Category
- Industrial Sub Category
- Scheduled sampling and shipping dates
- Sampling organization, contact, and telephone number
- Number and types of samples to be collected

When an authorized requestor schedules the sampling site, the SCC assigns an Episode number for the site (an Episode refers to a group of samples collected at a given plant or location within the same calendar week) and prepares a packet of materials to send to the Sampler. The packet normally contains the following:

- Episode Number assignments
- Laboratory assignments
- Traffic Report(s)
- Adhesive Sample Number Labels

SCC then creates a hardcopy Episode file and enters the scheduling information in the SAMTRAC (Sample Tracking) System.

Instructions for Completing Traffic Report

A separate Traffic Report (TR) (see Attachment 1), is to be completed for each shipment of samples to a laboratory. For samples going to EPA Contract laboratories use the TR provided by the SCC.

First, enter the Episode number on the top right corner of the TR form, where indicated. The Episode number is the identifying number that was assigned by SCC at the time the sampling was scheduled. This is followed by the Range of Sample numbers, which are assigned by the sampler when samples are packed for shipment to the laboratory(s).

Next, complete header information, excluding the grey areas on the top right of the form.

Along with the TR forms, the sampler will receive sequentially numbered sample labels from SCC. In order to protect the labels from water or solvent attack, labels on the sample container should be covered with clear, waterproof tape.

Enter the Sample numbers (from the labels) on the lower left side of the TR where indicated. Record all Sample numbers for samples included within the shipment. Extra numbered labels should be discarded and new strips of labels should be used for the next Episode of samples.

For each sample, indicate sample point description by checking the appropriate box. If additional sample point information is required enter it in the box labeled "Additional Sample Description" located in the center of the TR. Next record the physical parameters of the site at the time of sampling (i.e. pH, effluent flow, etc.). In the remaining boxes indicate what type of analysis the laboratory is to perform on a sample. Note: Analyses must be approved by EPA and requested through SCC at the time sampling is scheduled, to ensure that proper arrangements can be made in advance to accommodate the request.

The bottom two copies of the completed TR (pink and gold copies) must be included with the sample shipment to the laboratory. The TR should be enclosed in a clear plastic bag and securely taped to the underside of the lid of the shipping cooler.

Following sample shipment, distribute remaining TR copies as follows:

- Mail the top (white) copy to SCC at the address shown on the top of the TR form.
- The second (yellow) copy of TR form is retained by the sampler as the Region's file copy.

Procedures for Coordinating Sample Shipment

Immediately following sample shipment, call SCC and provide the following information:

- Sampler name and phone number
- Episode number
- Sampling date
- Sample numbers for samples included in each shipment
- Number of coolers per shipment
- Date of shipment
- Courier name and airbill number
- Type of shipment (e.g., overnight, two-day)
- Laboratory samples shipped to
- Any irregularities or anticipated problems with the samples
- Status of sampling project (e.g., final shipment, update of future shipping schedule)

SCC notifies the laboratory that samples are in transit and confirms arrival of the samples at the receiving laboratory. SCC assists in resolution of any problems concerning the samples, coordinating with the appropriate sampling personnel.

Upon sample receipt, the laboratory completes designated sections of the TR, recording date of sample receipt and sample condition, signs the TR, and returns the copy to SCC. SCC retains the laboratory-signed TR as written confirmation of sample receipt.

If you have any questions or comments regarding this information please call or write the Sample Control Center.

APPENDIX A

SEWER PIPELINES

(1) MINIMUM REQUIREMENTS FOR SEWER - PIPELINES

(a) Capacity:

Sewers shall be of such diameter as to pass without overflow, bypass, or back flow onto damageable property of a user the design peak flow including sewage and infiltration. All unavoidable inflow from roof, surface, footing, foundation, or other groundwater or surface water sources shall be excluded from capacity allowance.

(b) Velocity:

Sewers shall be designed to have a velocity to "self clean" or transport constituent solids to the treatment facility or the owner shall periodically service sewers to flush, transport, or remove solids from sewers with minimal velocity.

(2) GUIDELINES FOR SEWER PIPELINES

(a) Capacity:

(A) Collection sewers should be designed for the ultimate development of the tributary areas as determined by master sewerage and land use plans of the owner.

(B) The design of sewers should be based upon initial and ultimate flows. Flows should be broken down into domestic, industrial, and infiltration/inflow fractions. A peaking factor should be applied to domestic and industrial fractions.

(C) Domestic flows should be between 50 and 100 gallons per capita per day (gpcd). Peaking factors should be between 1.8 and 4.0. Infiltration allowance should be normally less than 2,000 gallons per acre per day; any greater allowance should be justified. Any significant inflow allowance should be justified.

(D) The minimum diameter of sewers should be 8 inches for maintenance purposes. Short nonextendable 6 inch sections of up to 250 feet are permissible.

(E) Replacement sewers should be designed commensurate with flow conditions.

(b) Velocity:

(A) Sewers should be laid on a gradient which will produce a mean velocity, when flowing full or half full, of at least (2) two feet per second, based upon the Manning formula with "n", the coefficient of roughness, valued at 0.013.

(b) Sewers with minimal flow such as upper

reaches of laterals or those sewers serving few dwellings should be steepened and/or reduced in diameter to approach a (2) two feet per second selfcleaning velocity. Actual flows during initial years of use should be carefully evaluated in this regard.

(C) Force mains and inverted siphons should be designed for (3) three feet per second at average flows.

(D) The minimum gradient for 8 inch sewers should be no less than 0.4 percent regardless of pipe material.

(E) The minimum gradient for 6 inch sewers should be no less than 0.6 percent, preferably 0.75 percent.

(F) The flow channel(s) through manhole bases should be smooth and conform to the shape and slope of the inlet sewer(s).

(G) Intersecting sewers, sewer connections, etc., should be made without causing backup into the smaller sewer. For intersecting unequal sized sewers in manholes, the elevation at 0.8 of full depth of flow in each sewer should match.

(c) Watertightness:

Completed sewer construction shall result in limited infiltration/exfiltration through pipe walls, joints, fittings, and connection fittings, etc., and no inflow. The limit shall be consistent with the pipe and manhole materials and with what is obtainable at the time by the construction industry on representative jobs for the same type of construction using high quality materials and state-of-the-art methods of workmanship. All completed sewer lines in new work shall be tested for watertightness using either recognized air or water testing requirements and procedures.

(c) Watertightness:

(A) Watertightness begins with good material and finally depends upon sound field practices. Good inspection and tests should be supplemented with an initial television inspection after trench backfilling is complete. Since many defects do not appear initially, an eleventh month final inspection should be performed where that capability is available and determined necessary to obtain acceptable in-place work. If only one television inspection is considered, the eleventh month inspection is recommended.

(B) Exfiltration testing or the low pressure air test for sanitary sewers should be a pres-

sure at least 6 feet greater than the groundwater conditions which the sewer is subject to at test time.

(C) Pipe materials, joints, fittings, and appurtenances should be selected for their watertight capabilities.

(D) Acceptance or performance standards should not necessarily be uniform for all pipe materials since average testing results with good workmanship for work will vary depending upon pipe materials. The range of allowable exfiltration/infiltration for work acceptance should be between 50 and 200 gallons per day per inch-of-diameter per mile (gpdidm). Nonporous (non-airpermeable) pipe should sustain pressure for twice the computed time for the same one pound per square inch (psi) air pressure drop required by the air test. Test sections should be from manhole-to-manhole or about 700 feet maximum.

(E) The watertightness of all building sewers should conform to the State Plumbing Code and be tested without exception.

(F) Manholes should be water tested for exfiltration during construction and/or visually inspected during first wet weather season after construction for infiltration. Leaks should be promptly repaired.

(G) Curved sewers should be as watertight as other sewers and be tested. While not recommended, horizontal/vertical curves at times may be allowed but should be limited in use. When used, the minimum radius of curvature should be not less than 200 feet and the maximum computed joint opening no more than 3/8 inch. Complete and accurate records should be kept of the exact location of such curved sewers for future reference. Reasonable field control should be exercised to not compound joint deflections and compromise watertightness.

(d) Structural Strength:

The completed installation including the excavated trench, the pipe, the bedding, and the pipe zone materials shall resist imposed loads from backfill, impact, and live loads (construction and design) without pipe failure through crushing, loss of watertightness, settlement, or significant capacity loss.

(d) Structural Strength:

(A) Bedding material should be placed full trench width from at least 4 inches under to spring line of all pipe for a leveling course and proper pipe support. Hand shaping of the native trench bottom for rigid pipe is not recommended but may be allowed, if appropriate, and uniform pipe support can be obtained and grade/ alignment can be maintained.

(B) Cantilevering of nonreinforced rigid pipe at manholes should be limited to the least distance practicable to make a flexible connection. A flexible joint should be within 12 inches of manhole for smaller pipe sizes. A second flexible joint should be provided within 4 feet of the manhole.

(C) Where cover from top of pipe to finished grade is less than 36 inches, special design and/or construction requirements should be considered including, but not limited to, raising finish grade, increasing class of pipe and/or pipe bedding, use of ductile iron, concrete encasement and restriction of construction equipment from travel over partially backfilled trench.

(e) Ability to Pass Solids:

Sewer systems shall be free of depressions, sharp edges, roughness, side sewer projections, obstructions, restrictions, displaced "0" rings, etc., which can cause solids to accumulate or deposit.

(e) Ability to Pass Solids:

(A) New sewers should be thoroughly flushed and visually inspected for accumulated debris prior to use.

(B) Building sewer connections should be made with fittings which prevent any projection into the main sewer. The main sewer should not be cracked, crushed, or otherwise damaged in making taps. All taps should be watertight.

(C) A tolerance for vertical deviation from true grade line should be plus or minus 0.02 feet. Depressions for solids deposition should be avoided. Similarly, the horizontal tolerance for deviation from line should be plus or minus 3/8 inch.

(D) Drop manhole piping should be easily maintained, self cleaning or able to "overflow" into the manhole. Pressure sewer piping connections, flow measuring devices, etc., in manholes should be designed to not obstruct flow.

(E) Flow channels in manholes should slope at least 0.1 feet from inlet to outlet.

(f) Durability:

(A) The materials and details of construction shall provide an inplace sewerage system which will resist corrosion of the pipe and manhole materials caused by any source or condition. Any corrosive effect shall be consistent with the design life of the sewer.

(B) Resistance to erosion of surfaces by grit, high velocity flow, etc., shall be addressed if appropriate.

(C) Temperature effect upon thermoplastic materials shall be appropriate.

(f) Durability:

(A) Sewers should be constructed of materials resistant to or protected from biological degradation, acid and alkaline solutions, normal sewer temperature variations, abrasion and industrial wastes (where applicable), or other harmful service conditions which may exist in the sewerage system.

The owner should have a user ordinance which restricts discharge of harmful substances into the sewerage system.

(B) Velocities over 15 feet per second in sewers should have special consideration for erosion control.

(g) Stability:

(A) Line and Grade: Horizontal alignment and vertical grade of inplace sewers upon construction completion and construction acceptance shall be relatively stable.

Design considerations, construction specifications, inspections, etc., shall preclude pipe settlement, shifting, or flotation such that capacity, watertightness structural integrity, ability to pass solids, maintainability, etc., are not compromised either at construction or any later time.

(B) Diameter: Rigid, flexible and

(g) Stability:

(A) Appropriate foundation stabilization or soils should be employed in unstable soils. Back fill should be in small lifts and compacted uniformly to specified density along and around the pipe.

(B) The Soil Class and density for bedding and pipe zone materials should be carefully selected and then compacted in the field to the required in-place density.

PVC and ABS composite sewer pipe should be deflection tested upon construction completion prior to acceptance with an approved nine blade go-no-go gauge. Initial deflection at construction completion should be no more than the following:

semiflexible pipes tend to lose minimum inside diameter if not designed and/or installed properly. Design considerations, construction specifications, field inspections, etc., shall preclude diameter loss such that capacity, watertightness, structural integrity, ability to pass solids, maintainability, etc., are not compromised either at construction or any later time.

(i) PVC (ASTM D-3034) sewer pipe should deflect no more than 4 to 5 percent based upon inside base diameters of 7.76, 9.71, 11.56 and 14.14 inches for 8, 10, 12, and 15 inch nominal pipe respectively.

(ii) ABS (ASTM D-2680) composite sewer pipe should deflect no more than 2 to 3 percent based upon inside average diameters of 7.75, 9.75, 11.75 and 14.75 inches for 8, 10, 12, and 15 inch nominal pipe respectively.

(C) Sewers on slopes over 25 percent should be evaluated for slippage or pipe bedding depending upon soil type, groundwater presence, construction conditions, etc. Appropriate anchors should be provided if necessary.

(h) Operation, Maintenance, and Safety:

Sewer systems require periodic and unscheduled maintenance for sustained operation. Designs shall conform to requirements of the sewage works owner for manhole construction, spacing, size, details and easements. All parts of the sewerage system shall be readily accessible. The minimum inside bottom diameter of manholes shall be 42 inches.

(h) Operation, Maintenance. and Safety:

(A) Access to the sewer by the sewer owner is essential to perform maintenance tasks. Easements should be granted along the sewer line to the system owner for any sewer for emergency repairs. Manholes and cleanouts are necessary for routine access. Structures should not be located over sewers.

(B) Owners should review own procedures, equipment, construction standards, etc., for sewer maintenance. Requirements of the owner should be obtained by designers upon start of sewer design since the owner must assume all future maintenance. Stricter standards of the owner should prevail if in conflict with these guidelines.

(C) General Manhole/Cleanout Standards for Sewers:

(i) The minimum inside bottom diameter should be no less than 48 inches. The least inside dimension may be reduced 38 inches where an integral

inside drop is acceptable to the owner. No more than one inside drop should be installed in a manhole.

(ii) Minimum cover opening diameter should be 22 inches.

(iii) Manholes should be located at:

(I) Every change in grade or alignment of sewer.

(II) Every point of change in size or elevation of sewer.

(III) Each intersection or junction of sewers.

(IV) Upper end of a lateral sewer.

(V) At intervals of 500 feet or less except for 24 inch and larger sewers.

(iv) Cleanouts should not be substituted for manholes except at the upper end of lateral sewers 250 feet or less in length.

(v) Channel width and depth should be equal pipe diameter. Manhole base ledges should be sloped to drain at least I in 12.

(vi) Access to manholes may be by portable ladder. Manhole rungs and in-place ladders which are subject to considerable corrosion and sliming are not recommended.

(vii) Where free fall of sewage into a manhole exceeds 24 inches from inlet pipe invert to manhole invert, an approved drop manhole should be used.

(D) Inverted Siphons:

Inverted siphons should include at least two pipe lines of such size and hydraulic gradient as to maintain a velocity of at least 3 feet per second in one pipe under conditions of average dry weather flow. Control manholes must be provided at both ends of the inverted siphon line. The inlet and outlet details shall be so arranged that the normal flow is diverted to either barrel so that the other barrel may be removed from service for maintenance.

(i) Separation of Water and Sewer Lines:

Protection of the water supply, be it distribution system, production facilities or source is not only prudent but mandatory and absolutely necessary.

Sanitary sewers and appurtenances thereto shall not physically connect to a public or private potable water supply system so as to permit the passage of any sewage or polluted water into the potable supply.

Sewer construction shall not disturb, degrade, or decrease the watertightness of any existing water supply line.

(i) Separation of Water and Sewer Lines:

(A) Parallel Water and Sewer Lines:

(i) Sewer lines should conform to Figure A-1.

(ii) Common trench construction for water and sewer should be avoided where practical. Where used, the minimum pipe separations of Figure A-1 should be maintained.

(B) Vertical Separation at Crossings of Water and Sewer Lines:

No special precautions should be necessary where top of sewer line is at least 1.5 feet below bottom of waterline and adequate structural protection for each line is provided.

(C) Exceptions: Use of Pressure Pipe Material for Sewer Line:

(i) Where the above horizontal or vertical separations cannot be maintained, the following pressure pipe materials should be used in addition to whatever waterline improvements or reconstruction that may be advisable or required for protection of water. The use of these pressure pipe materials from manhole-to-manhole is encouraged to avoid discontinuity

of materials.

(I) Ductile iron pipe, class 50, ANSI Standard A21.51 (AWWA C- 15 1) with either Push-on or mechanical rubber gasket joints in accordance with ANSI Standard A21. 11 (AWWA-C I 11).

(II) PVC pressure pipe, ASTM D-2241, SDR 32.5, (125 psi) with rubber-gasket joint in accordance with UNI-Bell Plastic Pipe Association recommended Standard Specification UNI-B-1 for a pressure-joint assembly.

(III) Asbestos-Cement pressure pipe, class 100, ASTMC-296 (AWWA C-400) with rubberring gaskets in accordance with ASTM D-1869

(IV) High density polyethylene pipe (Driscopipe 1000) PE 3406, minimum SDR 32.5, with butt fused joints.

(V) Other materials approved by the State Health Division.

(ii) At crossings requiring pressure pipe materials, the following should apply with one standard length of special pressure pipe centered over the waterline in all cases:

Pipe Material	Standard Pipe Length	Minimum Laying Length Each Side of Waterline Crossing
Ductile Iron	18 Feet	18 Feet
PVC	20 Feet	20 Feet
Asbestos-Cement	13 Feet	19 Feet
High-Density Polyethylene	38 Feet	19 Feet

(D) Soil Restoration at Crossings:

Soil removed in sewer line trench construction at waterline crossings where sewer crosses over water should be replaced in all areas to as near natural densities as possible through mechanical compaction to restore any natural resistance to groundwater movement which did exist prior to construction. Soil should include no rock fragments over 1-1/2 inch in the pipe zone.

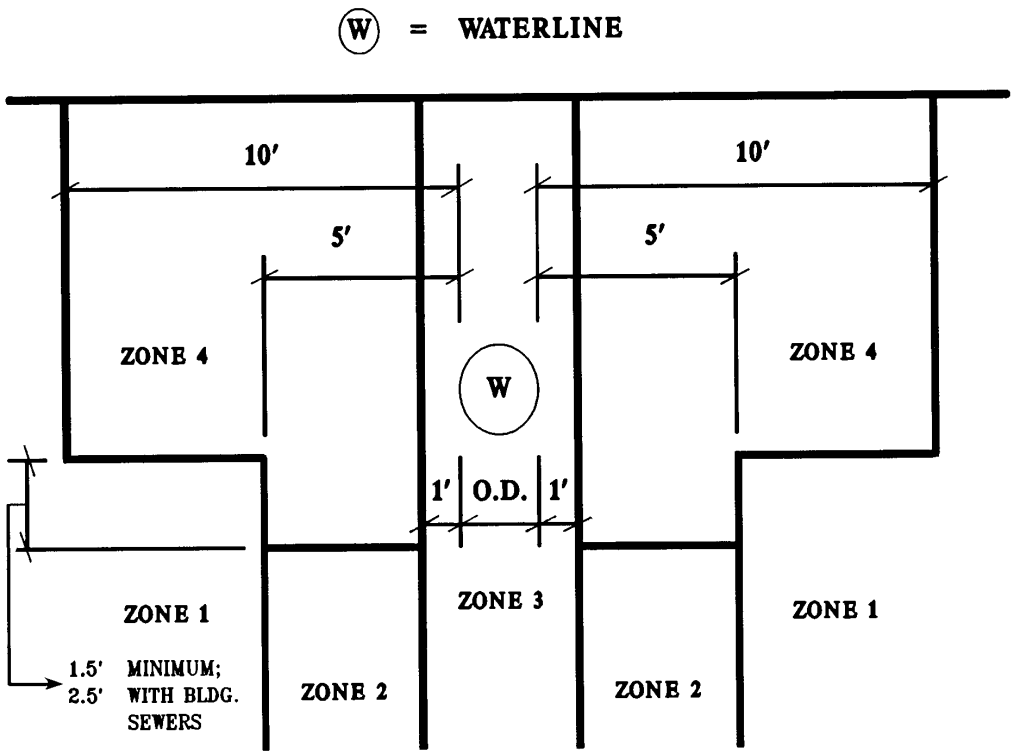
(E) Well Protection:

No sewer pipe should be laid less than 50 feet from any well without specific Health Division approval. Pressure pipe materials should be used to protect wells where minimum setbacks are not obtainable or where additional protection is required as determined by the State Health Division.

(F) Pipe Testing:

Whenever a pressure pipe material is used for any of the above purposes of separation, an appropriate pressure test should be conducted on the pressure pipe to confirm watertightness. Test pressures should be no less than 15 psig where use will be for a gravity sewer and higher where use will be for a pressure sewer (force main).

(G) Other Exceptions should be resolved jointly with the water purveyor and the State Health Division.



SEWER LINE ZONES

ZONE 1 SEWER LINE CAN BE LAID IN THIS AREA WITH NO SPECIAL REQUIREMENTS OF EITHER CONSTRUCTION OR MATERIALS.

ZONE 2 INSTALLING A SEWER LINE IN THIS ZONE IS NOT ADVISABLE AND MUST BE JUSTIFIED IN EACH CASE. WATER LINE SHOULD BE LOCATED ON A BENCH OF UNDISTURBED EARTH WHEN CONSTRUCTED CONCURRENTLY IN A COMMON TRENCH WITH SEWER LINE.

ZONE 3 INSTALLING A SEWER MAIN DIRECTLY OVER A WATER MAIN OR DIRECTLY UNDER A WATER MAIN IN THIS ZONE IS PROHIBITED SINCE TAPPING AND O. & M. OF EACH LINE WOULD BE IMPAIRED.

ZONE 4 SEWER LINE CONSTRUCTION IN THIS ZONE WOULD GENERALLY NOT BE PERMITTED. EACH INSTALLATION MUST BE JUSTIFIED. IF CONSTRUCTION WAS PERMITTED, PRESSURE PIPE MATERIALS FOR THIS SEWER LINE WOULD BE REQUIRED.

Effective 9/1/81

FIGURE A-1
SEPARATION OF PARALLEL WATER-SEWER LINES

APPENDIX B

RAW SEWAGE LIFT STATIONS

(1) MINIMUM REQUIREMENTS FOR RAW SEWAGE LIFT STATIONS

(a) Capacity:

Stations shall pass peak hourly flow including domestic, industrial and infiltration/inflow allowance.

(b) Solids Handling:

Pumping equipment shall pass at least 2-1/2 inch spheres. Valves, fittings etc., shall be capable of passing at least 3 inch spheres. Minimum force main size shall be 3 inches.

(c) Reliability:

(A) Mechanical reliability shall be achieved by redundant lift units such that the peak hourly flow can be passed with the largest unit out of service. Redundancy shall include check and gate valves and other 'common mode' failure sensitive items such as vacuum pumps or compressors on control systems.

(B)(i) Power outages shall result in no raw sewage discharges or bypasses to waters of the state based upon a predictable maximum period of power outage which will occur from year-to-year. Where such reliability does not exist, facilities and/or procedures shall be provided to prevent the discharge or bypass.

(2) GUIDELINES FOR RAW SEWAGE LIFT STATIONS

(a) Capacity:

Lift stations should be sized for the immediate flow requirement and expandable to the longrange (ultimate) requirement. Alternatively interim lift stations may be proposed if the date of expansion is unknowable or beyond the useful life of the lift station.

(b) Solids Handling:

All equipment should be sized to handle at least a 3-inch spheres. Force mains should be at least 4 inches in diameter.

(c) Reliability:

(A) Where no specific records exist, a four (4) hour minimum electrical power outage should be assumed.

(B) Events which should be excluded from design considerations are those which are rare, unusual, and cataclysmic in nature.

Means to prevent discharge or by pass include, but are not limited to, the following:

(i) Electric generator:

- Stationary or portable.
- Automatically or manually started.

(ii) Auxiliary fuel fired pump:

- Stationary or portable.

(C) Failure of prudent Operation and maintenance shall not be considered a valid reason for a station failure and resultant discharge or bypass.

(D) (i)Alarms shall be provided to all stations to announce at least high wet well conditions.

(ii) Telemetering to location with a 24-hour attendant shall be required in sensitive areas.

(d) Operation and Maintenance:

(A) Lift equipment shall be easily removable. Screwed fittings shall not be used for equipment removal. Lifting eyes or hoists shall be provided for equipment removal as appropriate.

(B) (i) A means to wash down wet wells shall be provided for all stations.

(ii) Potable water piped into wells or dry wells shall be equipped with a reduced pressure backflow prevention device.

(C) Wet wells shall have 'hopper

(iii) Storage:

- Sewer lines and manholes.
- Wet well.
- External basin.

(iv) Water supply reduction.

(C) (Future)

(D) (i) Alarms signals should be relayed to the sewer system owner in an effective manner.

(ii) Alarm should be actuated independently of the station control system. Example: Pumps are controlled by pneumatic system and separate float actuated alarm is provided.

(iii) Alarm power should have a battery powered backup electrical source.

(d) Operation and Maintenance:

(A) Flanged or bolted compressions fittings should be used for pump removal.

(B) Frequent wet well washdown should be assumed for all stations. A source of high volume wash water through a nozzle should be provided for this purpose at or on finish grade.

bottoms' at a slope of no flatter than one to one (1: 1), and flat bottom area shall be minimized to prevent deposition of solids.

(e) Safety:

(A) Wet and dry wells of all lift stations shall be considered manholes which will be entered by the owner's personnel.

(B) Each dry well shall have permanently installed ladder, lights, and forced fresh (out-side) air supply to the bottom of the well. Air supply shall be activated with light switch and intermittently operated with a timer.

(C) Wet wells including single well lift stations, shall have either installed or portable equipment for access, lighting, ventilation, etc., to be used when entered.

(e) Safety:

(A) No amount of safety equipment should replace basic safety procedures, knowledge, training and precautions.

(B) (i) Designers should follow appropriate safety codes.

(ii) Air supply should be sized for a least 30 air changes per hour where installed.

(C) (i) Frequently entered wet wells should have permanently installed equipment for access, lighting and ventilation, etc.

(ii) Infrequently entered wet wells may be served with portable equipment.

SITE EVALUATION AND EXISTING SYSTEM EVALUATION FEES

New Site Evaluation Fees. Fees in this section apply to each system for which site suitability is evaluated.	
Single family dwelling - First lot	$700
Single family dwelling - Each additional lot evaluated during initial visit	$700
Commercial facility with a design capacity of 1,000 gpd or less	$700
Commercial facility with a design capacity of 1,001-1,500 gpd	$882
Commercial facility with a design capacity of 1,501-2,000 gpd	$1,063
Commercial facility with a design capacity of 2,001-2,500 gpd	$1,244
Commercial facility s with a design capacity of 2,501-3,000 gpd	$1,426
Commercial facility with a design capacity of 3,001-3,500 gpd	$1,607
Commercial facility with a design capacity of 3,501-4,000 gpd	$1,788
Commercial facility with a design capacity of 4,001-4,500 gpd	$1,969
Commercial facility with a design capacity of 4,501-5,000 gpd	$2,151
Commercial facility with a design flow greater than 5,000 gpd	$2,373
Site Evaluation Report Review fee	$659
Existing System Evaluation Report fee	$659

TABLE 9B

PERMITTING FEES FOR SYSTEMS NOT SUBJECT TO WPCF PERMITS

Type of Fee		System Type					Plan Review fees for Commercial Facility Systems
		A	B	C	D	E	
Construction-Installation Permit Fees	For systems with a design capacity of less than 600 gpd	$461	$890	$1,038	$1,272	$1,566	$0
	For systems with a design capacity of 601-1,000 gpd	$461	$890	$1,038	$1,272	$1,566	$379
	For systems with a design capacity of 1,001-1,500 gpd	$560	$989	$1,137	$1,352	$1,710	$445
	For systems with a design capacity of 1,501-2,000 gpd	$659	$1,088	$1,236	$1,433	$1,763	$511
	For systems with a design capacity of 2,001-2,500 gpd	$758	$1,187	$1,335	$1,513	$1,862	$577
Reinspection fee		$103	$103	$103	$103	$103	$103
Pump Evaluation fee. For all permits that specify the use of a pump or dosing siphon except for sand filter, Alternative treatment technologies, Recirculating gravel filter, and pressurized distribution systems		$66	$66	$66	$66	$66	$66

System Type Key:
Type A = Gray Water waste disposal sumps
Type B = Holding tanks
Type C = Standard subsurface, Absorption trenches in saprolite, Redundant, Seepage trench, Steep slope
Type D = Alternative treatment technologies, Capping fill, Pressurized distribution, Tile dewatering
Type E = Recirculating gravel filter, Sand filter (commercial or residential)

Recycled Content Calculation Formula

The calculation for determining recycled content described in OAR 340-090-0360(2)(b) can be stated as the following formula:

$$\frac{\text{Recycled Material}}{\text{Total Plastic Material}} \text{ X } 100 = \text{Recycled Content}$$

OAR 340-093-0270
Standing Beneficial Use Determinations

Solid Waste	Beneficial Use	Conditions on Use
(a) Asphalt pavement or asphalt grindings from road projects	As asphalt and aggregate in new asphalt pavement or as fill within road prisms	Asphalt grindings must be compacted when used within road prisms
(b) Asphalt shingle waste from roof tear-offs and manufacturer scrap	As asphalt binder in asphalt mixtures	The waste does not contain asbestos or other non-asphalt shingle materials from roof tear-offs, such as nails, metal flashing, paper, or wood waste
(c) Dredged sediment approved by the department's water quality program for unconfined in-water placement based on chemical screening	Non-residential construction fill, surcharge, utility trench fill, or roadbase; habitat improvement, beach nourishment or other similar uses	A person using the material must submit a report to the Department in accordance with section (4) of this rule
(d) Dredged sediment not approved by the department's water quality program for in-water placement	Non-residential construction fill, utility trench fill, or roadbase	Concentrations of hazardous substances are below the higher of Department-approved human health occupational risk-based screening levels or naturally occurring background; placed where it will not be in contact with or adversely impact waters of the state; covered in a manner that minimizes exposure to ecological receptors; and a person using the material must submit a report to the Department in accordance with section (4) of this rule
(e) Foundry sand produced by iron, steel, or aluminum foundries	As aggregate in asphalt mixtures, concrete, Portland cement, or masonry mortar	None specified beyond the requirements of this rule
(f) Foundry sand produced by iron, steel, or aluminum foundries	Non-residential construction fill, utility trench fill, or roadbase	Concentrations of hazardous substances are below the higher of Department-approved human health occupational risk-based screening levels or naturally occurring background; placed where it will not be in contact with or adversely impact waters of the state; covered in a manner that minimizes exposure to ecological receptors; and a person using the material must submit a report to the Department in accordance with section (4) of this rule

OAR 340-093-0270
Standing Beneficial Use Determinations

Solid Waste	Beneficial Use	Conditions on Use
(g) Soil from cleanup sites	Non-residential construction fill, utility trench fill, or roadbase	Concentrations of hazardous substances are below the higher of Department-approved human health occupational risk-based screening levels or naturally occurring background; placed where it will not be in contact with or adversely impact waters of the state; covered in a manner that minimizes exposure to ecological receptors; the use is approved through Department Cleanup or Tanks Program cost recovery oversight; and a person using the material must submit a report to the Department in accordance with section (4) of this rule
(h) Soil from petroleum cleanup sites	As aggregate in asphalt mixtures	Petroleum contamination from releases of heating oil or motor fuel only
(i) Steel slag	As aggregate in asphalt mixtures, concrete, or Portland cement	None specified beyond the requirements of this rule
(j) Street sweeping fines	Spill response absorbent	After use of the waste a hazardous waste determination must be conducted and the material disposed at an appropriate permitted disposal site
(k) Street sweeping sand from winter storm applications	Road sanding	Swept up within 6 months of application or being re-exposed on the road after snowmelt; and the sand is separated from the street sweepings
(l) Wood-derived bottom ash, boiler rock, or clinkers, including rock, sand, dirt, and fused wood ash, from wood and wood waste fired boilers	As aggregate in asphalt mixtures, concrete, or Portland cement	None specified beyond the requirements of this rule

Toxicity Characteristic Leaching Procedure

METHOD 1311

TOXICITY CHARACTERISTIC LEACHING PROCEDURE

1.1 SCOPE AND APPLICATION

1.2 The TCLP is designed to determine the mobility of both organic and inorganic analytes present in liquid, solid, and multiphasic wastes.

1.3 If a total analysis of the waste demonstrates that individual analytes are not present in the waste, or that they are present but at such low concentrations that the appropriate regulatory levels could not possibly be exceeded, the TCLP need not be run.

1.4 If an analysis of any one of the liquid fractions of the TCLP extract indicates that a regulated compound is present at such high concentra- tions that, even after accounting for dilution from the other fractions of the extract, the concentration would be above the regulatory level for that compound, then the waste is hazardous and it is not necessary to analyze the remaining fractions of the extract.

1.5 If an analysis of extract obtained using a bottle extractor shows that the concentration of any regulated volatile analyte exceeds the regulatory level for that compound, then the waste is hazardous and extraction using the ZHE is not necessary. However, extract from a bottle extractor cannot be used to demonstrate that the concentration of volatile compounds is below the regulatory level.

2.1 SUMMARY OF METHOD

2.2 For liquid wastes (i.e., those containing less than 0.5% dry solid material), the waste, after filtration through a 0.6 to 0.8 µm glass fiber filter, is defined as the TCLP extract.

2.3 For wastes containing greater than or equal to 0.5% solids, the liquid, if any, is separated from the solid phase and stored for later analysis; the particle size of the solid phase is reduced, if necessary. The solid phase is extracted with an amount of extraction fluid equal to 20 times the weight of the solid phase. The extraction fluid employed is a function of the alkalinity of the solid phase of the waste. A special extractor vessel is used when testing for volatile analytes (see Table 1 for a list of volatile compounds). Following extraction, the liquid extract is separated from the solid phase by filtration through a 0.6 to 0.8 µm glass fiber filter.

2.4 If compatible (i.e., multiple phases will not form on combination), the initial liquid phase of the waste is added to the liquid extract, and these are analyzed together. If incompatible, the liquids are analyzed separately and the results are mathematically combined to yield a volume-weighted average concentration.

3.1 INTERFERENCES

3.2 Potential interferences that may be encountered during analysis are discussed in the individual analytical methods.

4.1 APPARATUS AND MATERIALS

4.2 Agitation apparatus: The agitation apparatus must be capable of rotating the extraction vessel in an end-over-end fashion (see Figure 1) at 30 ± 2 rpm. Suitable devices known to EPA are identified in Table 2.

4.3 Extraction Vessels

4.3.1 Zero-Headspace Extraction Vessel (ZHE). This device is for use only when the waste is being tested for the mobility of volatile analytes (i.e., those listed in Table 1). The ZHE (depicted in Figure 2) allows for liquid/solid separation within the device, and effectively precludes headspace. This type of vessel allows for initial liquid/solid separation, extraction, and final extract filtration without opening the vessel (see Section 4.3.1). The vessels shall have an internal volume of 500-600 mL, and be equipped to accommodate a 90-110 mm filter. The devices contain VITON®[1] O-rings which should be replaced frequently. Suitable ZHE devices known to EPA are identified in Table 3.

For the ZHE to be acceptable for use, the piston within the ZHE should be able to be moved with approximately 15 psi or less. If it takes more pressure to move the piston, the O-rings in the device should be replaced. If this does not solve the problem, the ZHE is unacceptable for TCLP analyses and the manufacturer should be contacted.

The ZHE should be checked for leaks after every extraction. If the device contains a built-in pressure gauge, pressurize the device to 50 psi, allow it to stand unattended for 1 hour, and recheck the pressure. If the device does not have a built-in pressure gauge, pressurize the device to 50 psi, submerge it in water, and check for the presence of air bubbles escaping from any of the fittings. If pressure is lost, check all fittings and inspect and replace O-rings, if necessary. Retest the device. If leakage problems cannot be solved, the manufacturer should be contacted.

Some ZHEs use gas pressure to actuate the ZHE piston, while others use mechanical pressure (see Table 3). Whereas the volatiles procedure (see Section 7.3) refers to pounds per square inch (psi), for the mechanically actuated piston, the pressure applied is measured in torque-inch-pounds. Refer to the manufacturer's instructions as to the proper conversion.

[1] VITON® is a trademark of Du Pont.

4.3.2 Bottle Extraction Vessel. When the waste is being evaluated using the nonvolatile extraction, a jar with sufficient capacity to hold the sample and the extraction fluid is needed. Headspace is allowed in this vessel.

The extraction bottles may be constructed from various materials, depending on the analytes to be analyzed and the nature of the waste (see Section 4.3.3). It is recommended that borosilicate glass bottles be used instead of other types of glass, especially when inorganics are of concern. Plastic bottles, other than polytetrafluoroethylene, shall not be used if organics are to be investigated. Bottles are available from a number of laboratory suppliers. When this type of extraction vessel is used, the filtration device discussed in Section 4.3.2 is used for initial liquid/solid separation and final extract filtration.

4.4 Filtration Devices: It is recommended that all filtrations be performed in a hood.

4.4.1 Zero-Headspace Extractor Vessel (ZHE): When the waste is evaluated for volatiles, the zero-headspace extraction vessel described in Section 4.2.1 is used for filtration. The device shall be capable of supporting and keeping in place the glass fiber filter and be able to withstand the pressure needed to accomplish separation (50 psi).

NOTE: When it is suspected that the glass fiber filter has been ruptured, an in-line glass fiber filter may be used to filter the material within the ZHE.

4.4.2 Filter Holder: When the waste is evaluated for other than volatile analytes, any filter holder capable of supporting a glass fiber filter and able to withstand the pressure needed to accomplish separation may be used. Suitable filter holders range from simple vacuum units to relatively complex systems capable of exerting pressures of up to 50 psi or more. The type of filter holder used depends on the properties of the material to be filtered (see Section 4.3.3). These devices shall have a minimum internal volume of 300 mL and be equipped to accommodate a minimum filter size of 47 mm (filter holders having an internal capacity of 1.5 L or greater, and equipped to accommodate a 142 mm diameter filter, are recommended). Vacuum filtration can only be used for wastes with low solids content (<10%) and for highly granular, liquid-containing wastes. All other types of wastes should be filtered using positive pressure filtration. Suitable filter holders known to EPA are shown in Table 4.

4.4.3 Materials of Construction: Extraction vessels and filtration devices shall be made of inert materials which will not leach or absorb waste components. Glass, polytetrafluoroethylene (PTFE), or type 316 stainless steel equipment may be used when evaluating the mobility of both organic and inorganic components. Devices made of high density polyethylene (HDPE), polypropylene (PP), or polyvinyl chloride (PVC) may be used only when evaluating the mobility of metals. Borosili-

water glass bottles are recommended for use over other types of glass bottles, especially when inorganics are analytes of concern.

4.5 Filters: Filters shall be made of borosilicate glass fiber, shall contain no binder materials, and shall have an effective pore size of 0.6 to 0.8 µm, or equivalent. Filters known to EPA which meet these specifications are identified in Table 5. Pre-filters must not be used. When evaluating the mobility of metals, filters shall be acid-washed prior to use by rinsing with 1N nitric acid followed by three consecutive rinses with deionized distilled water (a minimum of 1 L per rinse is recommended). Glass fiber filters are fragile and should be handled with care.

4.5 pH Meters: The meter should be accurate to ± 0.05 units at 25 °C.

4.6 ZHE Extract Collection Devices: TEDLAR®[2] bags or glass, stainless steel or PTFE gas-tight syringes are used to collect the initial liquid phase and the final extract of the waste when using the ZHE device. The devices listed are recommended for use under the following conditions:

4.6.1 If a waste contains an aqueous liquid phase or if a waste does not contain a significant amount of nonaqueous liquid (i.e., <1% of total waste), the TEDLAR® bag or a 600 mL syringe should be used to collect and combine the initial liquid and solid extract.

4.6.2 If a waste contains a significant amount of nonaqueous liquid in the initial liquid phase (i.e., >1% of total waste), the syringe or the TEDLAR® bag may be used for both the initial solid/liquid separation and the final extract filtration. However, analysts should use one or the other, not both.

4.6.3 If the waste contains no initial liquid phase (is 100% solid) or has no significant solid phase (is 100% liquid), either the TEDLAR® bag or the syringe may be used. If the syringe is used, discard the first 5 mL of liquid expressed from the device. The remaining aliquots are used for analysis.

4.7 ZHE Extraction Fluid Transfer Devices: Any device capable of transferring the extraction fluid into the ZHE without changing the nature of the extraction fluid is acceptable (e.g., a positive displacement or peristaltic pump, a gas tight syringe, pressure filtration unit (see Section 4.3.2), or other ZHE device).

4.8 Laboratory Balance: Any laboratory balance accurate to within ± 0.01 grams may be used (all weight measurements are to be within ± 0.1 grams).

4.9 Beaker or Erlenmeyer flask, glass, 500 mL.

---

[2] TEDLAR® is a registered trademark of Du Pont.

4.10 Watchglass, appropriate diameter to cover beaker or Erlenmeyer flask.

4.11 Magnetic stirrer.

5.1 REAGENTS

5.2 Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

5.3 Reagent Water. Reagent water is defined as water in which an interferant is not observed at or above the method's detection limit of the analyte(s) of interest. For nonvolatile extractions, ASTM Type II water or equivalent meets the definition of reagent water. For volatile extractions, it is recommended that reagent water be generated by any of the following methods. Reagent water should be monitored periodically for impurities.

5.3.1 Reagent water for volatile extractions may be generated by passing tap water through a carbon filter bed containing about 500 grams of activated carbon (Calgon Corp., Filtrasorb-300 or equivalent).

5.3.2 A water purification system (Millipore Super-Q or equivalent) may also be used to generate reagent water for volatile extractions.

5.3.3 Reagent water for volatile extractions may also be prepared by boiling water for 15 minutes. Subsequently, while maintaining the water temperature at 90 $\pm$ 5 degrees C, bubble a contaminant-free inert gas (e.g. nitrogen) through the water for 1 hour. While still hot, transfer the water to a narrow mouth screw-cap bottle under zero-headspace and seal with a Teflon-lined septum and cap.

5.4 Hydrochloric acid (1N), HCl, made from ACS reagent grade.

5.5 Nitric acid (1N), HNO_3, made from ACS reagent grade.

5.6 Sodium hydroxide (1N), NaOH, made from ACS reagent grade.

5.7 Glacial acetic acid, CH_3CH_2OOH, ACS reagent grade.

5.8 Extraction fluid.

5.8.1 Extraction fluid # 1: Add 5.7 mL glacial CH_3CH_2OOH to 500 mL of reagent water (See Section 5.2), add 64.3 mL of 1N NaOH, and dilute to a volume of 1 liter. When correctly prepared, the pH of this fluid will be 4.93 $\pm$ 0.05.

5.8.2 Extraction fluid # 2: Dilute 5.7 mL glacial CH_3CH_2OOH with reagent water (See Section 5.2) to a volume of 1 liter. When correctly prepared, the pH of this fluid will be 2.88 $\pm$ 0.05.

NOTE: These extraction fluids should be monitored frequently for impurities. The pH should be checked prior to use to ensure that these fluids are made up accurately. If impurities are found or the pH is not within the above specifications, the fluid shall be discarded and fresh extraction fluid prepared.

5.9 Analytical standards shall be prepared according to the appropriate analytical method.

6.1 SAMPLE COLLECTION, PRESERVATION, AND HANDLING

6.2 All samples shall be collected using an appropriate sampling plan.

6.3 The TCLP may place requirements on the minimal size of the field sample, depending upon the physical state or states of the waste and the analytes of concern. An aliquot is needed for preliminary evaluation of which extraction fluid is to be used for the nonvolatile analyte extraction procedure. Another aliquot may be needed to actually conduct the nonvolatile extraction (see Section 1.4 concerning the use of this extract for volatile organics). If volatile organics are of concern, another aliquot may be needed. Quality control measures may require additional aliquots. Further, it is always wise to collect more sample just in case something goes wrong with the initial attempt to conduct the test.

6.3 Preservatives shall not be added to samples before extraction.

6.4 Samples may be refrigerated unless refrigeration results in irreversible physical change to the waste. If precipitation occurs, the entire sample (including precipitate) should be extracted.

6.5 When the waste is to be evaluated for volatile analytes, care shall be taken to minimize the loss of volatiles. Samples shall be collected and stored in a manner intended to prevent the loss of volatile analytes (e.g., samples should be collected in Teflon-lined septum capped vials and stored at 4 °C. Samples should be opened only immediately prior to extraction).

6.6 TCLP extracts should be prepared for analysis and analyzed as soon as possible following extraction. Extracts or portions of extracts for metallic analyte determinations must be acidified with nitric acid to a pH < 2, unless precipitation occurs (see Section 7.2.14 if precipitation occurs). Extracts should be preserved for other analytes according to the guidance given in the individual analysis methods. Extracts or portions of extracts for organic analyte determinations shall not be allowed to come into contact with the atmosphere (i.e., no headspace) to prevent losses. See Section 8.0 (QA requirements) for acceptable sample and extract holding times.

7.2 Preliminary Evaluations

Perform preliminary TCLP evaluations on a minimum 100 gram aliquot of waste. This aliquot may not actually undergo TCLP extraction. These preliminary evaluations include: (1) determination of the percent solids (Section 7.1.1);
(2) determination of whether the waste contains insignificant solids and is, therefore, its own extract after filtration (Section 7.1.2); (3) determination of whether the solid portion of the waste requires particle size reduction (Section 7.1.3); and (4) determination of which of the two extraction fluids are to be used for the nonvolatile TCLP extraction of the waste (Section 7.1.4).

7.1.1 Preliminary determination of percent solids: Percent solids is defined as that fraction of a waste sample (as a percentage of the total sample) from which no liquid may be forced out by an applied pressure, as described below.

7.1.1.1 If the waste will obviously yield no liquid when subjected to pressure filtration (i.e., is 100% solids) proceed to Section 7.1.3.

7.1.1.2 If the sample is liquid or multiphasic, liquid/solid separation to make a preliminary determination of percent solids is required. This involves the filtration device described in Section 4.3.2 and is outlined in Sections 7.1.1.3 through 7.1.1.9.

7.1.1.3 Pre-weigh the filter and the container that will receive the filtrate.

7.1.1.4 Assemble the filter holder and filter following the manufacturer's instructions. Place the filter on the support screen and secure.

7.1.1.5 Weigh out a subsample of the waste (100 gram minimum) and record the weight.

7.1.1.6 Allow slurries to stand to permit the solid phase to settle. Wastes that settle slowly may be centrifuged prior to filtration. Centrifugation is to be used only as an aid to filtration. If used, the liquid should be decanted and filtered followed by filtration of the solid portion of the waste through the same filtration system.

7.1.1.7 Quantitatively transfer the waste sample to the filter holder (liquid and solid phases). Spread the waste sample evenly over the surface of the filter. If filtration of the waste at 4 °C reduces the amount of expressed liquid over what would be expressed at room temperature then allow the sample to warm up to room temperature in the device before filtering.

NOTE: If waste material (>1% of original sample weight) has obviously adhered to the container used to transfer the sample to the filtration apparatus, determine the weight of this residue and subtract it from the sample weight determined in Section 7.1.1.5 to determine the weight of the waste sample that will be filtered.

Gradually apply vacuum or gentle pressure of 1-10 psi, until air or pressurizing gas moves through the filter. If this point is not reached under 10 psi, and if no additional liquid has passed through the filter in any 2 minute interval, slowly increase the pressure in 10 psi increments to a maximum of 50 psi. After each incremental increase of 10 psi, if the pressurizing gas has not moved through the filter, and if no additional liquid has passed through the filter in any 2 minute interval, proceed to the next 10 psi increment. When the pressurizing gas begins to move through the filter, or when liquid flow has ceased at 50 psi (i.e., filtration does not result in any additional filtrate within any 2 minute period), stop the filtration.

NOTE: Instantaneous application of high pressure can degrade the glass fiber filter and may cause premature plugging.

7.1.1.8 The material in the filter holder is defined as the solid phase of the waste, and the filtrate is defined as the liquid phase.

NOTE: Some wastes, such as oily wastes and some paint wastes, will obviously contain some material that appears to be a liquid. Even after applying vacuum or pressure filtration, as outlined in Section 7.1.1.7, this material may not filter. If this is the case, the material within the filtration device is defined as a solid. Do not replace the original filter with a fresh filter under any circumstances. Use only one filter.

7.1.1.9 Determine the weight of the liquid phase by subtracting the weight of the filtrate container (see Section 7.1.1.3) from the total weight of the filtrate-filled container. Determine the weight of the solid phase of the waste sample by subtracting the weight of the liquid phase from the weight of the total waste sample, as determined in Section 7.1.1.5 or 7.1.1.7.

Record the weight of the liquid and solid phases. Calculate the percent solids as follows:

$$\text{Percent solids} = \frac{\text{Weight of solid (Section 7.1.1.9)}}{\text{Total weight of waste (Section 7.1.1.5 or 7.1.1.7)}} \times 100$$

7.1.2 If the percent solids determined in Section 7.1.1.9 is equal to or greater than 0.5%, then proceed either to Section 7.1.3 to

determine whether the solid material requires particle size reduction or to Section 7.1.2.1 if it is noticed that a small amount of the filtrate is entrained in wetting of the filter. If the percent solids determined in Section 7.1.1.9 is less than 0.5%, then proceed to Section 7.2.9 if the nonvolatile TCLP is to be performed and to Section 7.3 with a fresh portion of the waste if the volatile TCLP is to be performed.

7.1.2.1 Remove the solid phase and filter from the filtration apparatus.

7.1.2.2 Dry the filter and solid phase at 100 ± 20 °C until two successive weighing yield the same value within ± 1%. Record the final weight.

NOTE: Caution should be taken to ensure that the subject solid will not flash upon heating. It is recommended that the drying oven be vented to a hood or other appropriate device.

7.1.2.3 Calculate the percent dry solids as follows: (Wt. of dry waste + filter) - tared wt. of filter

$$\text{Percent dry solids} = \frac{\text{(Wt. of dry waste + filter) - tared wt. of filter}}{\text{Initial wt. of waste (Section 7.1.1.5 or 7.1.1.7)}} \times 100$$

7.1.2.4 If the percent dry solids is less than 0.5%, then proceed to Section 7.2.9 if the nonvolatile TCLP is to be performed, and to Section 7.3 if the volatile TCLP is to be performed. If the percent dry solids is greater than or equal to 0.5%, and if the nonvolatile TCLP is to be performed, return to the beginning of this Section (7.1) and, with a fresh portion of waste, determine whether particle size reduction is necessary (Section 7.1.3) and determine the appropriate extraction fluid (Section 7.1.4). If only the volatile TCLP is to be performed, see the note in Section 7.1.4.

7.1.3 Determination of whether the waste requires particle size reduction (particle size is reduced during this step): Using the solid portion of the waste, evaluate the solid for particle size. Particle size reduction is required, unless the solid has a surface area per gram of material equal to or greater than 3.1 cm^2, or is smaller than 1 cm in its narrowest dimension (i.e., is capable of passing through a 9.5 mm (0.375 inch) standard sieve). If the surface area is smaller or the particle size larger than described above, prepare the solid portion of the waste for extraction by crushing, cutting, or grinding the waste to a surface area or particle size as described above. If the solids are prepared for organic volatiles extraction, special precautions must be taken (see Section 7.3.6).

NOTE: Surface area criteria are meant for filamentous (e.g., paper, cloth, and similar) waste materials. Actual measurement of surface area is not required, nor is it recommended. For materials that do not obviously meet

the criteria, sample specific methods would need to be developed and employed to measure the surface area. Such methodology is currently not available.

7.1.4 Determination of appropriate extraction fluid: If the solid content of the waste is greater than or equal to 0.5% and if the sample will be extracted for nonvolatile constituents (Section 7.2), determine the appropriate fluid (Section 5.7) for the nonvolatiles extraction as follows:

NOTE: TCLP extraction for volatile constituents uses only extraction fluid #1 (Section 5.7.1). Therefore, if TCLP extraction for nonvolatiles is not required, proceed to Section 7.3.

7.1.4.1 Weigh out a small subsample of the solid phase of the waste, reduce the solid (if necessary) to a particle size of approximately 1 mm in diameter or less, and transfer 5.0 grams of the solid phase of the waste to a 500 mL beaker or Erlenmeyer flask.

7.1.4.2 Add 96.5 mL of reagent water to the beaker, cover with a watchglass, and stir vigorously for 5 minutes using a magnetic stirrer. Measure and record the pH. If the pH is <5.0, use extraction fluid #1. Proceed to Section 7.2.

7.1.4.3 If the pH from Section 7.1.4.2 is >5.0, add 3.5 mL 1N HCl, slurry briefly, cover with a watchglass, heat to 50 °C, and hold at 50 °C for 10 minutes.

7.1.4.4 Let the solution cool to room temperature and record the pH. If the pH is <5.0, use extraction fluid #1. If the pH is >5.0, use extraction fluid #2. Proceed to Section 7.2.

7.1.5 If the aliquot of the waste used for the preliminary evaluation (Sections 7.1.1 - 7.1.4) was determined to be 100% solid at Section 7.1.1.1, then it can be used for the Section 7.2 extraction (assuming at least 100 grams remain), and the Section 7.3 extraction (assuming at least 25 grams remain). If the aliquot was subjected to the procedure in Section 7.1.1.7, then another aliquot shall be used for the volatile extraction procedure in Section 7.3. The aliquot of the waste subjected to the procedure in Section 7.1.1.7 might be appropriate for use for the Section 7.2 extraction if an adequate amount of solid (as determined by Section 7.1.1.9) was obtained. The amount of solid necessary is dependent upon whether a sufficient amount of extract will be produced to support the analyses. If an adequate amount of solid remains, proceed to Section 7.2.10 of the nonvolatile TCLP extraction.

7.2 Procedure When Volatiles are not Involved

A minimum sample size of 100 grams (solid and liquid phases) is recommend- ed. In some cases, a larger sample size may be appropriate, depending on the

solids content of the waste sample (percent solids, See Section 7.1.1), whether the initial liquid phase of the waste will be miscible with the aqueous extract of the solid, and whether inorganics, semivolatile organics, pesticides, and herbicides are all analytes of concern. Enough solids should be generated for extraction such that the volume of TCLP extract will be sufficient to support all of the analyses required. If the amount of extract generated by a single TCLP extraction will not be sufficient to perform all of the analyses, more than one extraction may be performed and the extracts from each combined and aliquoted for analysis.

7.2.1 If the waste will obviously yield no liquid when subjected to pressure filtration (i.e., is 100% solid, see Section 7.1.1), weigh out a subsample of the waste (100 gram minimum) and proceed to Section 7.2.9.

7.2.2 If the sample is liquid or multiphasic, liquid/solid separation is required. This involves the filtration device described in Section 4.3.2 and is outlined in Sections 7.2.3 to 7.2.8.

7.2.3 Pre-weigh the container that will receive the filtrate.

7.2.4 Assemble the filter holder and filter following the manufacturer's instructions. Place the filter on the support screen and secure. Acid wash the filter if evaluating the mobility of metals (see Section 4.4).

NOTE: Acid washed filters may be used for all nonvolatile extractions even when metals are not of concern.

7.2.5 Weigh out a subsample of the waste (100 gram minimum) and record the weight. If the waste contains <0.5% dry solids (Section 7.1.2), the liquid portion of the waste, after filtration, is defined as the TCLP extract. Therefore, enough of the sample should be filtered so that the amount of filtered liquid will support all of the analyses required of the TCLP extract. For wastes containing >0.5% dry solids (Sections 7.1.1 or 7.1.2), use the percent solids information obtained in Section 7.1.1 to determine the optimum sample size (100 gram minimum) for filtration. Enough solids should be generated by filtration to support the analyses to be performed on the TCLP extract.

7.2.6 Allow slurries to stand to permit the solid phase to settle. Wastes that settle slowly may be centrifuged prior to filtration. Use centrifugation only as an aid to filtration. If the waste is centrifuged, the liquid should be decanted and filtered followed by filtration of the solid portion of the waste through the same filtration system.

7.2.7 Quantitatively transfer the waste sample (liquid and solid phases) to the filter holder (see Section 4.3.2). Spread the waste sample evenly over the surface of the filter. If filtration of the waste at 4 °C reduces the amount of expressed liquid over what would be expressed at

room temperature, then allow the sample to warm up to room temperature in the device before filtering.

NOTE: If waste material (>1% of the original sample weight) has obviously adhered to the container used to transfer the sample to the filtration apparatus, determine the weight of this residue and subtract it from the sample weight determined in Section 7.2.5, to determine the weight of the waste sample that will be filtered.

Gradually apply vacuum or gentle pressure of 1-10 psi, until air or pressurizing gas moves through the filter. If this point is not reached under 10 psi, and if no additional liquid has passed through the filter in any 2 minute interval, slowly increase the pressure in 10 psi increments to a maximum of 50 psi. After each incremental increase of 10 psi, if the pressurizing gas has not moved through the filter, and if no additional liquid has passed through the filter in any 2 minute interval, proceed to the next 10 psi increment. When the pressurizing gas begins to move through the filter, or when the liquid flow has ceased at 50 psi (i.e., filtration does not result in any additional filtrate within a 2 minute period), stop the filtration.

NOTE: Instantaneous application of high pressure can degrade the glass fiber filter and may cause premature plugging.

7.2.8 The material in the filter holder is defined as the solid phase of the waste, and the filtrate is defined as the liquid phase. Weigh the filtrate. The liquid phase may now be either analyzed (See Section 7.2.12) or stored at 4 °C until time of analysis.

NOTE: Some wastes, such as oily wastes and some paint wastes, will obviously contain some material that appears to be a liquid. Even after applying vacuum or pressure filtration, as outlined in Section 7.2.7, this material may not filter. If this is the case, the material within the filtration device is defined as a solid and is carried through the extraction as a solid. Do not replace the original filter with a fresh filter under any circumstances. Use only one filter.

7.2.9 If the waste contains <0.5% dry solids (see Section 7.1.2), proceed to Section 7.2.13. If the waste contains >0.5% dry solids (see Section 7.1.1 or 7.1.2), and if particle size reduction of the solid was needed in Section 7.1.3, proceed to Section 7.2.10. If the waste as received passes a 9.5 mm sieve, quantitatively transfer the solid material into the extractor bottle along with the filter used to separate the initial liquid from the solid phase, and proceed to Section 7.2.11.

7.2.10 Prepare the solid portion of the waste for extraction by crushing, cutting, or grinding the waste to a surface area or particle size as described in Section 7.1.3. When the surface area or particle size has been appropriately altered, quantitatively transfer the solid

material into an extractor bottle. Include the filter used to separate the initial liquid from the solid phase.

NOTE: Sieving of the waste is not normally required. Surface area requirements are meant for filamentous (e.g., paper, cloth) and similar waste materials. Actual measurement of surface area is not recommended. If sieving is necessary, a Teflon coated sieve should be used to avoid contamination of the sample.

7.2.11 Determine the amount of extraction fluid to add to the extractor vessel as follows:

$$\text{Weight of extraction fluid} = \frac{20 \times \text{percent solids (Section 7.1.1)} \times \text{weight of waste filtered (Section 7.2.5 or 7.2.7)}}{100}$$

Slowly add this amount of appropriate extraction fluid (see Section 7.1.4) to the extractor vessel. Close the extractor bottle tightly (it is recommended that Teflon tape be used to ensure a tight seal), secure in rotary agitation device, and rotate at 30 ± 2 rpm for 18 ± 2 hours. Ambient temperature (i.e., temperature of room in which extraction takes place) shall be maintained at 23 ± 2 °C during the extraction period.

NOTE: As agitation continues, pressure may build up within the extractor bottle for some types of wastes (e.g., limed or calcium carbonate containing waste may evolve gases such as carbon dioxide). To relieve excess pressure, the extractor bottle may be periodically opened (e.g., after 15 minutes, 30 minutes, and 1 hour) and vented into a hood.

7.2.12 Following the 18 ± 2 hour extraction, separate the material in the extractor vessel into its component liquid and solid phases by filtering through a new glass fiber filter, as outlined in Section 7.2.7. For final filtration of the TCLP extract, the glass fiber filter may be changed, if necessary, to facilitate filtration. Filter(s) shall be acid-washed (see Section 4.4) if evaluating the mobility of metals.

7.2.13 Prepare the TCLP extract as follows:

7.2.13.1 If the waste contained no initial liquid phase, the filtered liquid material obtained from Section 7.2.12 is defined as the TCLP extract. Proceed to Section 7.2.14.

7.2.13.2 If compatible (e.g., multiple phases will not result on combination), combine the filtered liquid resulting from Section 7.2.12 with the initial liquid phase of the waste obtained in Section 7.2.7. This combined liquid is defined as the TCLP extract. Proceed to Section 7.2.14.

7.2.13.3 If the initial liquid phase of the waste, as obtained from Section 7.2.7, is not or may not be compatible with the filtered liquid resulting from Section 7.2.12, do not combine these liquids. Analyze these liquids, collectively defined as the TCLP extract, and combine the results mathematically, as described in Section 7.2.14.

7.2.14 Following collection of the TCLP extract, the pH of the extract should be recorded. Immediately aliquot and preserve the extract for analysis. Metals aliquots must be acidified with nitric acid to pH <2. If precipitation is observed upon addition of nitric acid to a small aliquot of the extract, then the remaining portion of the extract for metals analyses shall not be acidified and the extract shall be analyzed as soon as possible. All other aliquots must be stored under refrigeration (4 °C) until analyzed. The TCLP extract shall be prepared and analyzed according to appropriate analytical methods. TCLP extracts to be analyzed for metals shall be acid digested except in those instances where digestion causes loss of metallic analytes. If an analysis of the undigested extract shows that the concentration of any regulated metallic analyte exceeds the regulatory level, then the waste is hazardous and digestion of the extract is not necessary. However, data on undigested extracts alone cannot be used to demonstrate that the waste is not hazardous. If the individual phases are to be analyzed separately, determine the volume of the individual phases (to $\pm$ 0.5%), conduct the appropriate analyses, and combine the results mathematically by using a simple volume-weighted average:

$$\text{Final Analyte Concentration} = \frac{(V_1)(C_1) + (V_2)(C_2)}{V_1 + V_2}$$

where:

V_1 = The volume of the first phase (L).
C_1 = The concentration of the analyte of concern in the first phase (mg/L).
V_2 = The volume of the second phase (L).
C_2 = The concentration of the analyte of concern in the second phase (mg/L).

7.2.15 Compare the analyte concentrations in the TCLP extract with the levels identified in the appropriate regulations. Refer to Section 8.0 for quality assurance requirements.

7.3 Procedure When Volatiles are Involved

Use the ZHE device to obtain TCLP extract for analysis of volatile compounds only. Extract resulting from the use of the ZHE shall not be used to evaluate the mobility of nonvolatile analytes (e.g., metals, pesticides, etc.).

The ZHE device has approximately a 500 mL internal capacity. The ZHE can thus accommodate a maximum of 25 grams of solid (defined as that fraction of a

sample from which no additional liquid may be forced out by an applied pressure of 50 psi), due to the need to add an amount of extraction fluid equal to 20 times the weight of the solid phase.

Charge the ZHE with sample only once and do not open the device until the final extract (of the solid) has been collected. Repeated filling of the ZHE to obtain 25 grams of solid is not permitted.

Do not allow the waste, the initial liquid phase, or the extract to be exposed to the atmosphere for any more time than is absolutely necessary. Any manipulation of these materials should be done when cold (4 °C) to minimize loss of volatiles.

7.3.1 Pre-weigh the (evacuated) filtrate collection container (See Section 4.6) and set aside. If using a TEDLAR® bag, express all liquid from the ZHE device into the bag, whether for the initial or final liquid/solid separation, and take an aliquot from the liquid in the bag for analysis. The containers listed in Section 4.6 are recommended for use under the conditions stated in Sections 4.6.1 - 4.6.3.

7.3.2 Place the ZHE piston within the body of the ZHE (it may be helpful first to moisten the piston O-rings slightly with extraction fluid). Adjust the piston within the ZHE body to a height that will minimize the distance the piston will have to move once the ZHE is charged with sample (based upon sample size requirements determined from Section 7.3, Section 7.1.1 and/or 7.1.2). Secure the gas inlet/outlet flange (bottom flange) onto the ZHE body in accordance with the manufacturer's instructions. Secure the glass fiber filter between the support screens and set aside. Set liquid inlet/outlet flange (top flange) aside.

7.3.3 If the waste is 100% solid (see Section 7.1.1), weigh out a subsample (25 gram maximum) of the waste, record weight, and proceed to Section 7.3.5.

7.3.4 If the waste contains < 0.5% dry solids (Section 7.1.2), the liquid portion of waste, after filtration, is defined as the TCLP extract. Filter enough of the sample so that the amount of filtered liquid will support all of the volatile analyses required. For wastes containing $\geq$ 0.5% dry solids (Sections 7.1.1 and/or 7.1.2), use the percent solids information obtained in Section 7.1.1 to determine the optimum sample size to charge into the ZHE. The recommended sample size is as follows:

7.3.4.1 For wastes containing < 5% solids (see Section 7.1.1), weigh out a 500 gram subsample of waste and record the weight.

7.3.4.2 For wastes containing $\geq$ 5% solids (see Section 7.1.1), determine the amount of waste to charge into the ZHE as follows:

$$\text{Weight of waste to charge ZHE} = \frac{25}{\text{percent solids (Section 7.1.1)}} \times 100$$

Weigh out a subsample of the waste of the appropriate size and record the weight.

7.3.5 If particle size reduction of the solid portion of the waste was required in Section 7.1.3, proceed to Section 7.3.6. If particle size reduction was not required in Section 7.1.3, proceed to Section 7.3.7.

7.3.6 Prepare the waste for extraction by crushing, cutting, or grinding the solid portion of the waste to a surface area or particle size as described in Section 7.1.3. Wastes and appropriate reduction equipment should be refrigerated, if possible, to 4 °C prior to particle size reduction. The means used to effect particle size reduction must not generate heat in and of itself. If reduction of the solid phase of the waste is necessary, exposure of the waste to the atmosphere should be avoided to the extent possible.

NOTE: Sieving of the waste is not recommended due to the possibility that volatiles may be lost. The use of an appropriately graduated ruler is recommended as an acceptable alternative. Surface area requirements are meant for filamentous (e.g., paper, cloth) and similar waste materials. Actual measurement of surface area is not recommended.

When the surface area or particle size has been appropriately altered, proceed to Section 7.3.7.

7.3.7 Waste slurries need not be allowed to stand to permit the solid phase to settle. Do not centrifuge wastes prior to filtration.

7.3.8 Quantitatively transfer the entire sample (liquid and solid phases) quickly to the ZHE. Secure the filter and support screens onto the top flange of the device and secure the top flange to the ZHE body in accordance with the manufacturer's instructions. Tighten all ZHE fittings and place the device in the vertical position (gas inlet/outlet flange on the bottom). Do not attach the extract collection device to the top plate.

NOTE: If waste material (>1% of original sample weight) has obviously adhered to the container used to transfer the sample to the ZHE, determine the weight of this residue and subtract it from the sample weight determined in Section 7.3.4 to determine the weight of the waste sample that will be filtered.

Attach a gas line to the gas inlet/outlet valve (bottom flange) and, with the liquid inlet/outlet valve (top flange) open, begin applying gentle pressure of 1-10 psi (or more if necessary) to force all headspace

slowly out of the ZHE device into a hood. At the first appearance of liquid from the liquid inlet/outlet valve, quickly close the valve and discontinue pressure. If filtration of the waste at 4 °C reduces the amount of expressed liquid over what would be expressed at room tempera- ture, then allow the sample to warm up to room temperature in the device before filtering. If the waste is 100% solid (see Section 7.1.1), slowly increase the pressure to a maximum of 50 psi to force most of the headspace out of the device and proceed to Section 7.3.12.

7.3.9 Attach the evacuated pre-weighed filtrate collection container to the liquid inlet/outlet valve and open the valve. Begin applying gentle pressure of 1-10 psi to force the liquid phase of the sample into the filtrate collection container. If no additional liquid has passed through the filter in any 2 minute interval, slowly increase the pressure in 10 psi increments to a maximum of 50 psi. After each incremental increase of 10 psi, if no additional liquid has passed through the filter in any 2 minute interval, proceed to the next 10 psi increment. When liquid flow has ceased such that continued pressure filtration at 50 psi does not result in any additional filtrate within a 2 minute period, stop the filtration. Close the liquid inlet/outlet valve, discontinue pressure to the piston, and disconnect and weigh the filtrate collection container.

NOTE: Instantaneous application of high pressure can degrade the glass fiber filter and may cause premature plugging.

7.3.10 The material in the ZHE is defined as the solid phase of the waste and the filtrate is defined as the liquid phase.

NOTE: Some wastes, such as oily wastes and some paint wastes, will obviously contain some material that appears to be a liquid. Even after applying pressure filtration, this material will not filter. If this is the case, the material within the filtration device is defined as a solid and is carried through the TCLP extraction as a solid.

If the original waste contained <0.5% dry solids (see Section 7.1.2), this filtrate is defined as the TCLP extract and is analyzed directly. Proceed to Section 7.3.15.

7.3.11 The liquid phase may now be either analyzed immediately (See Sections 7.3.13 through 7.3.15) or stored at 4 °C under minimal headspace conditions until time of analysis. Determine the weight of extraction fluid #1 to add to the ZHE as follows:

$$\text{Weight of extraction fluid} = \frac{20 \times \text{percent solids (Section 7.1.1)} \times \text{weight of waste filtered (Section 7.3.4 or 7.3.8)}}{100}$$

7.3.12 The following Sections detail how to add the appropriate amount of extraction fluid to the solid material within the ZHE and agitation of the ZHE vessel. Extraction fluid #1 is used in all cases (See Section 5.7).

7.3.12.1 With the ZHE in the vertical position, attach a line from the extraction fluid reservoir to the liquid in- let/outlet valve. The line used shall contain fresh extraction fluid and should be preflushed with fluid to eliminate any air pockets in the line. Release gas pressure on the ZHE piston (from the gas inlet/outlet valve), open the liquid inlet/outlet valve, and begin transferring extraction fluid (by pumping or similar means) into the ZHE. Continue pumping extraction fluid into the ZHE until the appropriate amount of fluid has been introduced into the device.

7.3.12.2 After the extraction fluid has been added, immediately close the liquid inlet/outlet valve and disconnect the extraction fluid line. Check the ZHE to ensure that all valves are in their closed positions. Manually rotate the device in an end-over-end fashion 2 or 3 times. Reposition the ZHE in the vertical position with the liquid inlet/outlet valve on top. Pressurize the ZHE to 5-10 psi (if necessary) and slowly open the liquid inlet/outlet valve to bleed out any headspace (into a hood) that may have been introduced due to the addition of extraction fluid. This bleeding shall be done quickly and shall be stopped at the first appearance of liquid from the valve. Re-pressurize the ZHE with 5-10 psi and check all ZHE fittings to ensure that they are closed.

7.3.12.3 Place the ZHE in the rotary agitation appara- tus (if it is not already there) and rotate at 30 $\pm$ 2 rpm for 18 $\pm$ 2 hours. Ambient temperature (i.e., temperature of room in which extraction occurs) shall be maintained at 23 $\pm$ 2 °C during agita- tion.

7.3.13 Following the 18 $\pm$ 2 hour agitation period, check the pressure behind the ZHE piston by quickly opening and closing the gas inlet/outlet valve and noting the escape of gas. If the pressure has not been maintained (i.e., no gas release observed), the device is leaking. Check the ZHE for leaking as specified in Section 4.2.1, and perform the extraction again with a new sample of waste. If the pressure within the device has been maintained, the material in the extractor vessel is once again separated into its component liquid and solid phases. If the waste contained an initial liquid phase, the liquid may be filtered directly into the same filtrate collection container (i.e., TEDLAR® bag) holding the initial liquid phase of the waste. A separate filtrate collection container must be used if combining would create multiple phases, or there is not enough volume left within the filtrate collection container. Filter through the glass fiber filter, using the ZHE device as discussed in Section 7.3.9. All extract shall be filtered and collected if the

TEDLAR® bag is used, if the extract is multiphasic, or if the waste contained an initial liquid phase (see Sections 4.6 and 7.3.1).

NOTE: An in-line glass fiber filter may be used to filter the material within the ZHE if it is suspected that the glass fiber filter has been ruptured.

7.3.14 If the original waste contained no initial liquid phase, the filtered liquid material obtained from Section 7.3.13 is defined as the TCLP extract. If the waste contained an initial liquid phase, the filtered liquid material obtained from Section 7.3.13 and the initial liquid phase (Section 7.3.9) are collectively defined as the TCLP extract.

7.3.15 Following collection of the TCLP extract, immediately prepare the extract for analysis and store with minimal headspace at 4 °C until analyzed. Analyze the TCLP extract according to the appropriate analytical methods. If the individual phases are to be analyzed separately (i.e., are not miscible), determine the volume of the individual phases (to 0.5%), conduct the appropriate analyses, and combine the results mathematically by using a simple volume-weighted average:

$$\text{Final Analyte Concentration} = \frac{(V_1)(C_1) + (V_2)(C_2)}{V_1 + V_2}$$

where:

V_1 = The volume of the first phases (L).
C_1 = The concentration of the analyte of concern in the first phase (mg/L).
V_2 = The volume of the second phase (L).
C_2 = The concentration of the analyte of concern in the second phase (mg/L).

7.3.16 Compare the analyte concentrations in the TCLP extract with the levels identified in the appropriate regulations. Refer to Section 8.0 for quality assurance requirements.

8.1 QUALITY ASSURANCE

8.2 A minimum of one blank (using the same extraction fluid as used for the samples) must be analyzed for every 20 extractions that have been conducted in an extraction vessel.

8.3 A matrix spike shall be performed for each waste type (e.g., wastewater treatment sludge, contaminated soil, etc.) unless the result exceeds the regulatory level and the data are being used solely to demonstrate that the waste property exceeds the regulatory level. A minimum of one matrix spike must be analyzed for each analytical batch. As a minimum, follow the matrix spike addition guidance provided in each analytical method.

8.3.1 Matrix spikes are to be added after filtration of the TCLP extract and before preservation. Matrix spikes should not be added prior to TCLP extraction of the sample.

8.3.2 In most cases, matrix spikes should be added at a concentration equivalent to the corresponding regulatory level. If the analyte concentration is less than one half the regulatory level, the spike concentration may be as low as one half of the analyte concentra- tion, but may not be not less than five times the method detection limit. In order to avoid differences in matrix effects, the matrix spikes must be added to the same nominal volume of TCLP extract as that which was analyzed for the unspiked sample.

8.3.3 The purpose of the matrix spike is to monitor the performance of the analytical methods used, and to determine whether matrix interferences exist. Use of other internal calibration methods, modification of the analytical methods, or use of alternate analytical methods may be needed to accurately measure the analyte concentration in the TCLP extract when the recovery of the matrix spike is below the expected analytical method performance.

8.3.4 Matrix spike recoveries are calculated by the following formula:

$$\%R\ (\%Recovery) = 100\ (X_s - X_u)/K$$

where:
X_s = measured value for the spiked sample,
X_u = measured value for the unspiked sample, and
K = known value of the spike in the sample.

8.4 All quality control measures described in the appropriate analytical methods shall be followed.

8.5 The use of internal calibration quantitation methods shall be employed for a metallic contaminant if: (1) Recovery of the contaminant from the TCLP extract is not at least 50% and the concentration does not exceed the regulatory level, and (2) The concentration of the contaminant measured in the extract is within 20% of the appropriate regulatory level.

8.4.1. The method of standard additions shall be employed as the internal calibration quantitation method for each metallic contaminant.

8.4.2 The method of standard additions requires preparing calibration standards in the sample matrix rather than reagent water or blank solution. It requires taking four identical aliquots of the solution and adding known amounts of standard to three of these aliquots. The forth aliquot is the unknown. Preferably, the first addition should be prepared so that the resulting concentration is approximately 50% of the expected concentration of the sample. The second and third additions should be prepared so that the concentrations are approximately 100% and

150% of the expected concentration of the sample. All four aliquots are maintained at the same final volume by adding reagent water or a blank solution, and may need dilution adjustment to maintain the signals in the linear range of the instrument technique. All four aliquots are analyzed.

8.4.3 Prepare a plot, or subject data to linear regression, of instrument signals or external-calibration-derived concentrations as the dependant variable (y-axis) versus concentrations of the additions of standard as the independent variable (x-axis). Solve for the intercept of the abscissa (the independent variable, x-axis) which is the concentration in the unknown.

8.4.4 Alternately, subtract the instrumental signal or external- calibration-derived concentration of the unknown (unspiked) sample from the instrumental signals or external-calibration-derived concentrations of the standard additions. Plot or subject to linear regression of the corrected instrument signals or external-calibration-derived concentra- tions as the dependant variable versus the independent variable. Derive concentrations for unknowns using the internal calibration curve as if it were an external calibration curve.

8.5 Samples must undergo TCLP extraction within the following time periods:

SAMPLE MAXIMUM HOLDING TIMES [DAYS]

	From: Field collection To: TCLP extraction	From: TCLP extraction To: Preparative extraction	From: Preparative extraction To: Determinative analysis	Total elapsed time
Volatiles	14	NA	14	28
Semi-volatiles	14	7	40	61
Mercury	28	NA	28	56
Metals, except mercury	180	NA	180	360

NA = Not applicable

If sample holding times are exceeded, the values obtained will be considered minimal concentrations. Exceeding the holding time is not acceptable in establishing that a waste does not exceed the regulatory level. Exceeding the holding time will not invalidate characterization if the waste exceeds the regulatory level.

9.1 METHOD PERFORMANCE

9.2 Ruggedness. Two ruggedness studies have been performed to determine the effect of various perturbations on specific elements of the TCLP protocol. Ruggedness testing determines the sensitivity of small procedural variations which might be expected to occur during routine laboratory application.

9.2.1 Metals - The following conditions were used when leaching a waste for metals analysis:

Varying Conditions	
Liquid/Solid ratio	19:1 vs. 21:1
Extraction time	16 hours vs. 18 hours
Headspace	20% vs. 60%
Buffer #2 acidity	190 meq vs. 210 meq
Acid-washed filters	yes vs. no
Filter type	0.7 µm glass fiber vs. 0.45 µm vs. polycarbonate
Bottle type	borosilicate vs. flint glass

Of the seven method variations examined, acidity of the extraction fluid had the greatest impact on the results. Four of 13 metals from an API separator sludge/electroplating waste (API/EW) mixture and two of three metals from an ammonia lime still bottom waste were extracted at higher levels by the more acidic buffer. Because of the sensitivity to pH changes, the method requires that the extraction fluids be prepared so that the final pH is within $\pm$ 0.05 units as specified.

9.2.2 Volatile Organic Compounds - The following conditions were used when leaching a waste for VOC analysis:

Varying Conditions	
Liquid/Solid ratio	19:1 vs. 21:1
Headspace	0% vs. 5%
Buffer #1 acidity	60 meq vs. 80 meq
Method of storing extract	Syringe vs. Tedlar® bag
Aliquotting	yes vs. no
Pressure behind piston	0 psi vs. 20 psi

None of the parameters had a significant effect on the results of the ruggedness test.

9.3 Precision. Many TCLP precision (reproducibility) studies have been performed, and have shown that, in general, the precision of the TCLP is comparable to or exceeds that of the EP toxicity test and that method precision is adequate. One of the more significant contributions to poor precision appears to be related to sample homogeneity and inter-laboratory variation (due to the nature of waste materials).

9.3.1 Metals - The results of a multi-laboratory study are shown in Table 6, and indicate that a single analysis of a waste may not be adequate for waste characterization and identification requirements.

9.3.2 Semi-Volatile Organic Compounds - The results of two studies are shown in Tables 7 and 8. Single laboratory precision was excellent with greater than 90 percent of the results exhibiting an RSD less than 25 percent. Over 85 percent of all individual compounds in the multi-laboratory study fell in the RSD range of 20 - 120 percent. Both studies concluded that the TCLP provides adequate precision. It was also determined that the high acetate content of the extraction fluid did not present problems (i.e., column degradation of the gas chromatograph) for the analytical conditions used.

9.3.3 Volatile Organic Compounds - Eleven laboratories participated in a collaborative study of the use of the ZHE with two waste types which were fortified with a mixture of VOCs. The results of the collaborative study are shown in Table 9. Precision results for VOCs tend to occur over a considerable range. However, the range and mean RSD compared very closely to the same collaborative study metals results in Table 6. Blackburn and Show concluded that at the 95% level of signifi- cance: 1) recoveries among laboratories were statistically similar, 2) recoveries did not vary significantly between the two sample types, and 3) each laboratory showed the same pattern of recovery for each of the two samples.

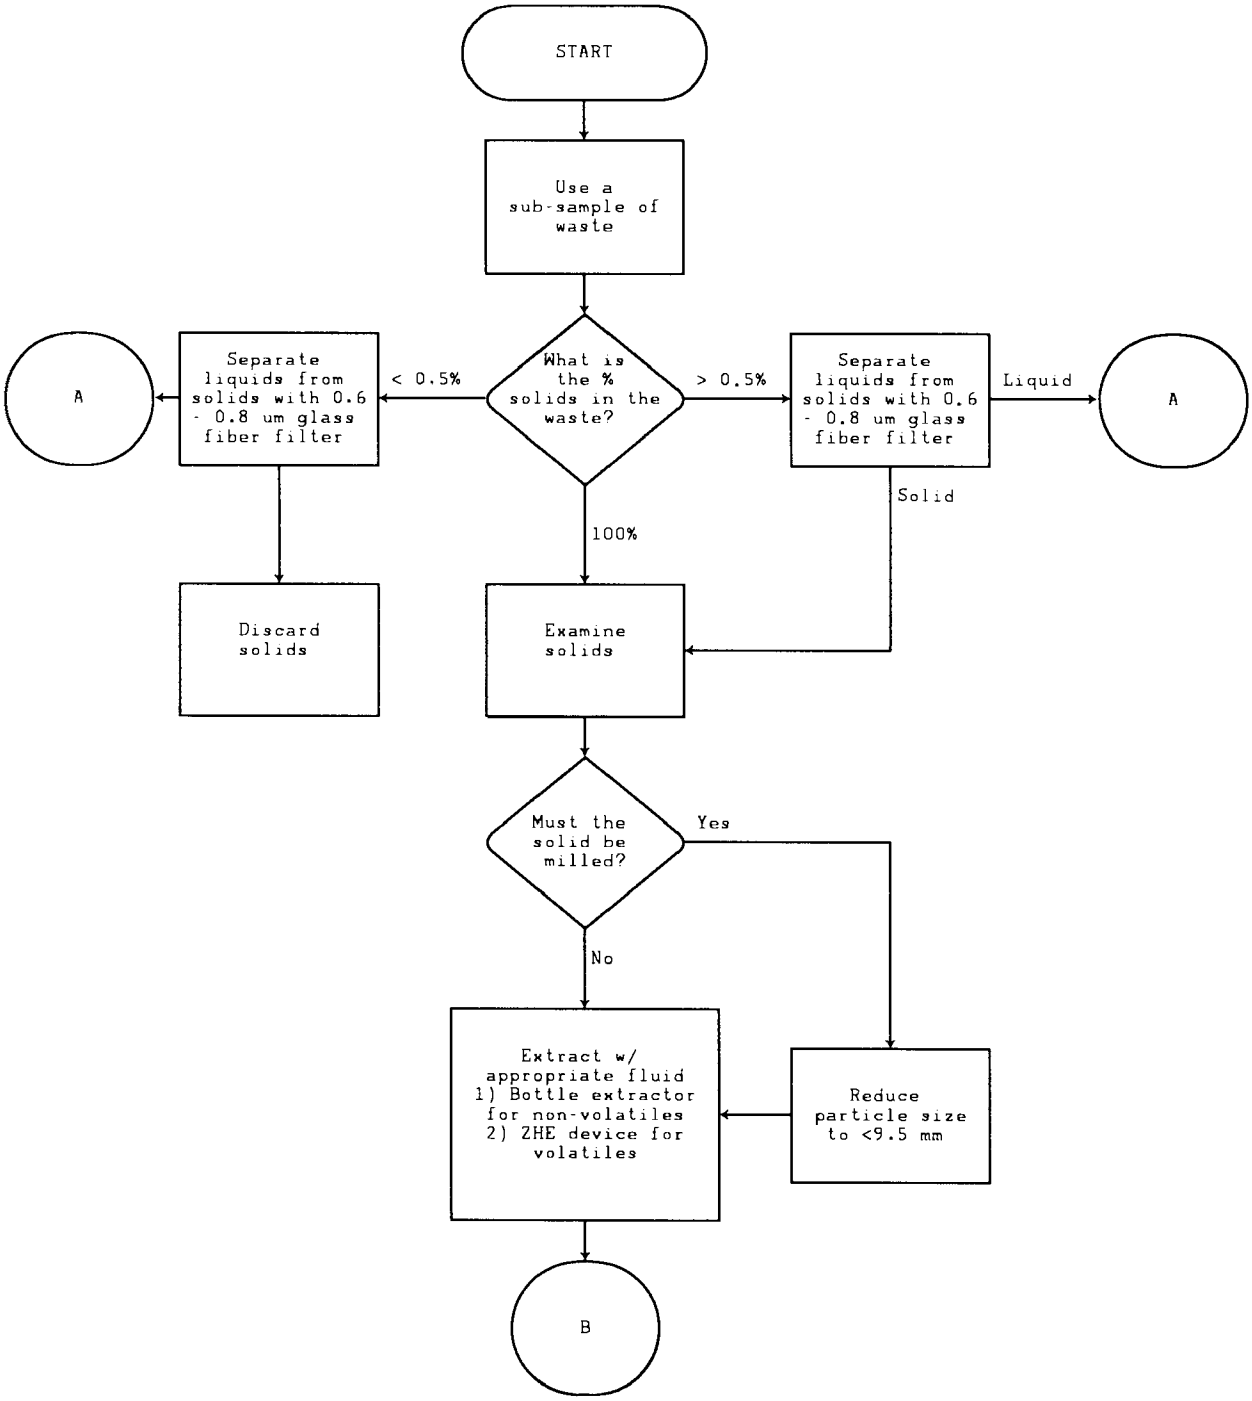
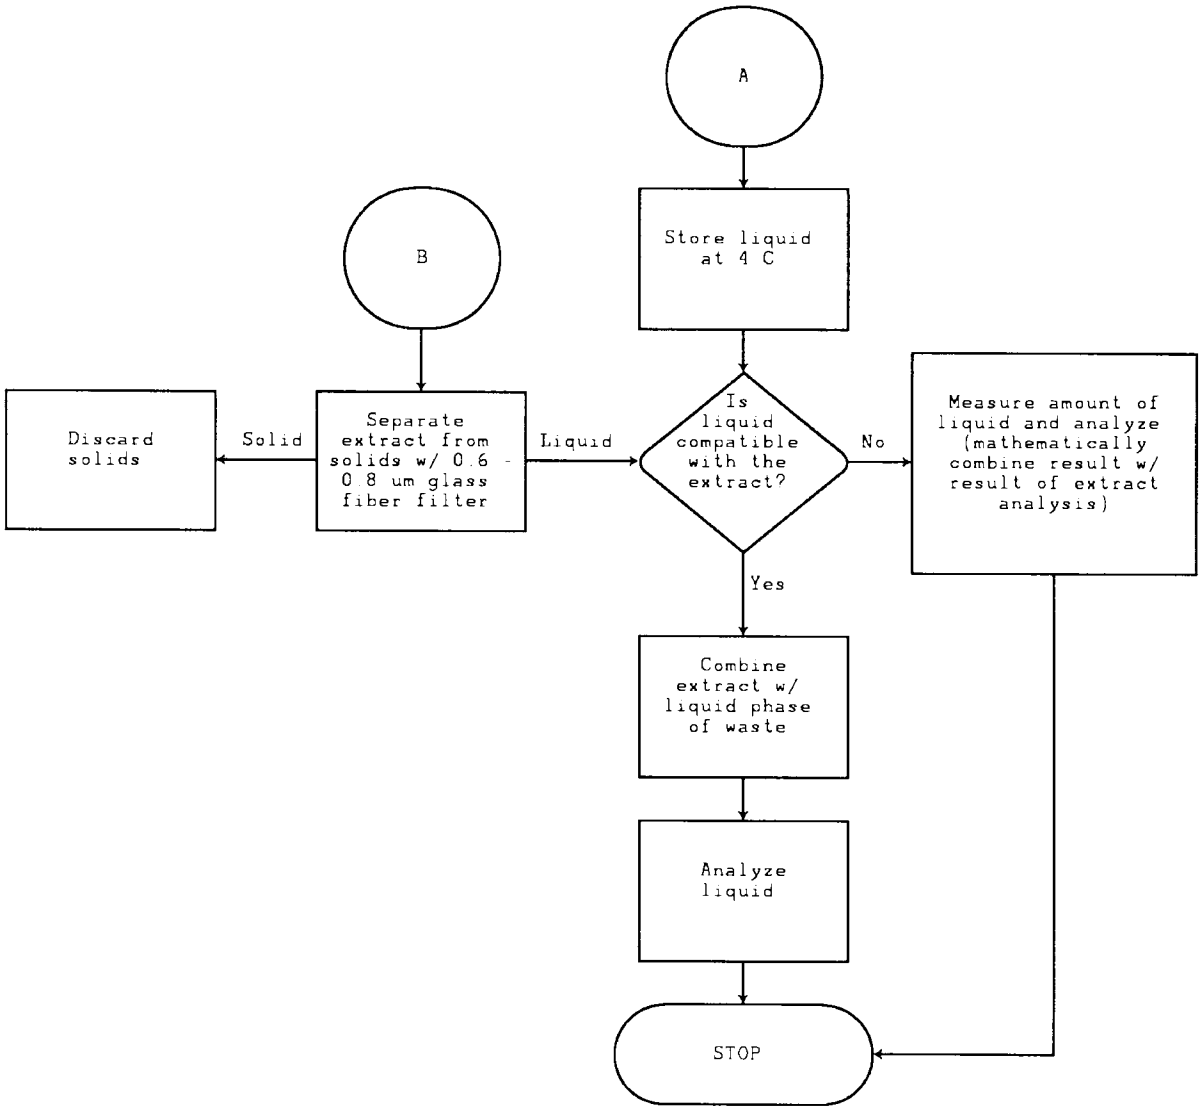
TOXICITY CHARACTERISTIC LEACHATE PROCEDURE



CHARACTERISTIC LEACHATE PROCEDURE



OAR 340-095-0020

Toxicity Characteristic Leaching Procedure

METHOD 1311

TOXICITY CHARACTERISTIC LEACHING PROCEDURE

1.1 SCOPE AND APPLICATION

1.2 The TCLP is designed to determine the mobility of both organic and inorganic analytes present in liquid, solid, and multiphasic wastes.

1.3 If a total analysis of the waste demonstrates that individual analytes are not present in the waste, or that they are present but at such low concentrations that the appropriate regulatory levels could not possibly be exceeded, the TCLP need not be run.

1.4 If an analysis of any one of the liquid fractions of the TCLP extract indicates that a regulated compound is present at such high concentra- tions that, even after accounting for dilution from the other fractions of the extract, the concentration would be above the regulatory level for that compound, then the waste is hazardous and it is not necessary to analyze the remaining fractions of the extract.

1.5 If an analysis of extract obtained using a bottle extractor shows that the concentration of any regulated volatile analyte exceeds the regulatory level for that compound, then the waste is hazardous and extraction using the ZHE is not necessary. However, extract from a bottle extractor cannot be used to demonstrate that the concentration of volatile compounds is below the regulatory level.

2.1 SUMMARY OF METHOD

2.2 For liquid wastes (i.e., those containing less than 0.5% dry solid material), the waste, after filtration through a 0.6 to 0.8 µm glass fiber filter, is defined as the TCLP extract.

2.3 For wastes containing greater than or equal to 0.5% solids, the liquid, if any, is separated from the solid phase and stored for later analysis; the particle size of the solid phase is reduced, if necessary. The solid phase is extracted with an amount of extraction fluid equal to 20 times the weight of the solid phase. The extraction fluid employed is a function of the alkalinity of the solid phase of the waste. A special extractor vessel is used when testing for volatile analytes (see Table 1 for a list of volatile compounds). Following extraction, the liquid extract is separated from the solid phase by filtration through a 0.6 to 0.8 µm glass fiber filter.

2.4 If compatible (i.e., multiple phases will not form on combination), the initial liquid phase of the waste is added to the liquid extract, and these are analyzed together. If incompatible, the liquids are analyzed separately and the results are mathematically combined to yield a volume-weighted average concentration.

3.1 INTERFERENCES

3.2 Potential interferences that may be encountered during analysis are discussed in the individual analytical methods.

4.1 APPARATUS AND MATERIALS

4.2 Agitation apparatus: The agitation apparatus must be capable of rotating the extraction vessel in an end-over-end fashion (see Figure 1) at 30 ± 2 rpm. Suitable devices known to EPA are identified in Table 2.

4.3 Extraction Vessels

4.3.1 Zero-Headspace Extraction Vessel (ZHE). This device is for use only when the waste is being tested for the mobility of volatile analytes (i.e., those listed in Table 1). The ZHE (depicted in Figure 2) allows for liquid/solid separation within the device, and effectively precludes headspace. This type of vessel allows for initial liquid/solid separation, extraction, and final extract filtration without opening the vessel (see Section 4.3.1). The vessels shall have an internal volume of 500-600 mL, and be equipped to accommodate a 90-110 mm filter. The devices contain VITON®[1] O-rings which should be replaced frequently. Suitable ZHE devices known to EPA are identified in Table 3.

For the ZHE to be acceptable for use, the piston within the ZHE should be able to be moved with approximately 15 psi or less. If it takes more pressure to move the piston, the O-rings in the device should be replaced. If this does not solve the problem, the ZHE is unacceptable for TCLP analyses and the manufacturer should be contacted.

The ZHE should be checked for leaks after every extraction. If the device contains a built-in pressure gauge, pressurize the device to 50 psi, allow it to stand unattended for 1 hour, and recheck the pressure. If the device does not have a built-in pressure gauge, pressurize the device to 50 psi, submerge it in water, and check for the presence of air bubbles escaping from any of the fittings. If pressure is lost, check all fittings and inspect and replace O-rings, if necessary. Retest the device. If leakage problems cannot be solved, the manufacturer should be contacted.

Some ZHEs use gas pressure to actuate the ZHE piston, while others use mechanical pressure (see Table 3). Whereas the volatiles procedure (see Section 7.3) refers to pounds per square inch (psi), for the mechanically actuated piston, the pressure applied is measured in torque-inch-pounds. Refer to the manufacturer's instructions as to the proper conversion.

[1] VITON® is a trademark of Du Pont.

4.3.2 Bottle Extraction Vessel. When the waste is being evaluated using the nonvolatile extraction, a jar with sufficient capacity to hold the sample and the extraction fluid is needed. Headspace is allowed in this vessel.

The extraction bottles may be constructed from various materials, depending on the analytes to be analyzed and the nature of the waste (see Section 4.3.3). It is recommended that borosilicate glass bottles be used instead of other types of glass, especially when inorganics are of concern. Plastic bottles, other than polytetrafluoroethylene, shall not be used if organics are to be investigated. Bottles are available from a number of laboratory suppliers. When this type of extraction vessel is used, the filtration device discussed in Section 4.3.2 is used for initial liquid/solid separation and final extract filtration.

4.4 Filtration Devices: It is recommended that all filtrations be performed in a hood.

4.4.1 Zero-Headspace Extractor Vessel (ZHE): When the waste is evaluated for volatiles, the zero-headspace extraction vessel described in Section 4.2.1 is used for filtration. The device shall be capable of supporting and keeping in place the glass fiber filter and be able to withstand the pressure needed to accomplish separation (50 psi).

NOTE: When it is suspected that the glass fiber filter has been ruptured, an in-line glass fiber filter may be used to filter the material within the ZHE.

4.4.2 Filter Holder: When the waste is evaluated for other than volatile analytes, any filter holder capable of supporting a glass fiber filter and able to withstand the pressure needed to accomplish separation may be used. Suitable filter holders range from simple vacuum units to relatively complex systems capable of exerting pressures of up to 50 psi or more. The type of filter holder used depends on the properties of the material to be filtered (see Section 4.3.3). These devices shall have a minimum internal volume of 300 mL and be equipped to accommodate a minimum filter size of 47 mm (filter holders having an internal capacity of 1.5 L or greater, and equipped to accommodate a 142 mm diameter filter, are recommended). Vacuum filtration can only be used for wastes with low solids content (<10%) and for highly granular, liquid-containing wastes. All other types of wastes should be filtered using positive pressure filtration. Suitable filter holders known to EPA are shown in Table 4.

4.4.3 Materials of Construction: Extraction vessels and filtration devices shall be made of inert materials which will not leach or absorb waste components. Glass, polytetrafluoroethylene (PTFE), or type 316 stainless steel equipment may be used when evaluating the mobility of both organic and inorganic components. Devices made of high density polyethylene (HDPE), polypropylene (PP), or polyvinyl chloride (PVC) may be used only when evaluating the mobility of metals. Borosili-

Outer glass bottles are recommended for use over other types of glass bottles, especially when inorganics are analytes of concern.

4.5 Filters: Filters shall be made of borosilicate glass fiber, shall contain no binder materials, and shall have an effective pore size of 0.6 to 0.8 µm, or equivalent. Filters known to EPA which meet these specifications are identified in Table 5. Pre-filters must not be used. When evaluating the mobility of metals, filters shall be acid-washed prior to use by rinsing with 1N nitric acid followed by three consecutive rinses with deionized distilled water (a minimum of 1 L per rinse is recommended). Glass fiber filters are fragile and should be handled with care.

4.5 pH Meters: The meter should be accurate to ± 0.05 units at 25 °C.

4.6 ZHE Extract Collection Devices: TEDLAR®[2] bags or glass, stainless steel or PTFE gas-tight syringes are used to collect the initial liquid phase and the final extract of the waste when using the ZHE device. The devices listed are recommended for use under the following conditions:

4.6.1 If a waste contains an aqueous liquid phase or if a waste does not contain a significant amount of nonaqueous liquid (i.e., <1% of total waste), the TEDLAR® bag or a 600 mL syringe should be used to collect and combine the initial liquid and solid extract.

4.6.2 If a waste contains a significant amount of nonaqueous liquid in the initial liquid phase (i.e., >1% of total waste), the syringe or the TEDLAR® bag may be used for both the initial solid/liquid separation and the final extract filtration. However, analysts should use one or the other, not both.

4.6.3 If the waste contains no initial liquid phase (is 100% solid) or has no significant solid phase (is 100% liquid), either the TEDLAR® bag or the syringe may be used. If the syringe is used, discard the first 5 mL of liquid expressed from the device. The remaining aliquots are used for analysis.

4.7 ZHE Extraction Fluid Transfer Devices: Any device capable of transferring the extraction fluid into the ZHE without changing the nature of the extraction fluid is acceptable (e.g., a positive displacement or peristaltic pump, a gas tight syringe, pressure filtration unit (see Section 4.3.2), or other ZHE device).

4.8 Laboratory Balance: Any laboratory balance accurate to within ± 0.01 grams may be used (all weight measurements are to be within ± 0.1 grams).

4.9 Beaker or Erlenmeyer flask, glass, 500 mL.

---

[2] TEDLAR® is a registered trademark of Du Pont.

4.10 Watchglass, appropriate diameter to cover beaker or Erlenmeyer flask.

4.11 Magnetic stirrer.

5.1 REAGENTS

5.2 Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

5.3 Reagent Water. Reagent water is defined as water in which an interferant is not observed at or above the method's detection limit of the analyte(s) of interest. For nonvolatile extractions, ASTM Type II water or equivalent meets the definition of reagent water. For volatile extractions, it is recommended that reagent water be generated by any of the following methods. Reagent water should be monitored periodically for impurities.

5.3.1 Reagent water for volatile extractions may be generated by passing tap water through a carbon filter bed containing about 500 grams of activated carbon (Calgon Corp., Filtrasorb-300 or equivalent).

5.3.2 A water purification system (Millipore Super-Q or equivalent) may also be used to generate reagent water for volatile extractions.

5.3.3 Reagent water for volatile extractions may also be prepared by boiling water for 15 minutes. Subsequently, while maintaining the water temperature at 90 $\pm$ 5 degrees C, bubble a contaminant-free inert gas (e.g. nitrogen) through the water for 1 hour. While still hot, transfer the water to a narrow mouth screw-cap bottle under zero-headspace and seal with a Teflon-lined septum and cap.

5.4 Hydrochloric acid (1N), HCl, made from ACS reagent grade.

5.5 Nitric acid (1N), HNO_3, made from ACS reagent grade.

5.6 Sodium hydroxide (1N), NaOH, made from ACS reagent grade.

5.7 Glacial acetic acid, CH_3CH_2OOH, ACS reagent grade.

5.8 Extraction fluid.

5.8.1 Extraction fluid # 1: Add 5.7 mL glacial CH_3CH_2OOH to 500 mL of reagent water (See Section 5.2), add 64.3 mL of 1N NaOH, and dilute to a volume of 1 liter. When correctly prepared, the pH of this fluid will be 4.93 $\pm$ 0.05.

5.8.2 Extraction fluid # 2: Dilute 5.7 mL glacial CH_3CH_2OOH with reagent water (See Section 5.2) to a volume of 1 liter. When correctly prepared, the pH of this fluid will be 2.88 $\pm$ 0.05.

NOTE: These extraction fluids should be monitored frequently for impurities. The pH should be checked prior to use to ensure that these fluids are made up accurately. If impurities are found or the pH is not within the above specifications, the fluid shall be discarded and fresh extraction fluid prepared.

5.9 Analytical standards shall be prepared according to the appropriate analytical method.

6.1 SAMPLE COLLECTION, PRESERVATION, AND HANDLING

6.2 All samples shall be collected using an appropriate sampling plan.

6.3 The TCLP may place requirements on the minimal size of the field sample, depending upon the physical state or states of the waste and the analytes of concern. An aliquot is needed for preliminary evaluation of which extraction fluid is to be used for the nonvolatile analyte extraction procedure. Another aliquot may be needed to actually conduct the nonvolatile extraction (see Section 1.4 concerning the use of this extract for volatile organics). If volatile organics are of concern, another aliquot may be needed. Quality control measures may require additional aliquots. Further, it is always wise to collect more sample just in case something goes wrong with the initial attempt to conduct the test.

6.3 Preservatives shall not be added to samples before extraction.

6.4 Samples may be refrigerated unless refrigeration results in irreversible physical change to the waste. If precipitation occurs, the entire sample (including precipitate) should be extracted.

6.5 When the waste is to be evaluated for volatile analytes, care shall be taken to minimize the loss of volatiles. Samples shall be collected and stored in a manner intended to prevent the loss of volatile analytes (e.g., samples should be collected in Teflon-lined septum capped vials and stored at 4 °C. Samples should be opened only immediately prior to extraction).

6.6 TCLP extracts should be prepared for analysis and analyzed as soon as possible following extraction. Extracts or portions of extracts for metallic analyte determinations must be acidified with nitric acid to a pH < 2, unless precipitation occurs (see Section 7.2.14 if precipitation occurs). Extracts should be preserved for other analytes according to the guidance given in the individual analysis methods. Extracts or portions of extracts for organic analyte determinations shall not be allowed to come into contact with the atmosphere (i.e., no headspace) to prevent losses. See Section 8.0 (QA requirements) for acceptable sample and extract holding times.

7.2 Preliminary Evaluations

Perform preliminary TCLP evaluations on a minimum 100 gram aliquot of waste. This aliquot may not actually undergo TCLP extraction. These preliminary evaluations include: (1) determination of the percent solids (Section 7.1.1);
(2) determination of whether the waste contains insignificant solids and is, therefore, its own extract after filtration (Section 7.1.2); (3) determination of whether the solid portion of the waste requires particle size reduction (Section 7.1.3); and (4) determination of which of the two extraction fluids are to be used for the nonvolatile TCLP extraction of the waste (Section 7.1.4).

7.1.1 Preliminary determination of percent solids: Percent solids is defined as that fraction of a waste sample (as a percentage of the total sample) from which no liquid may be forced out by an applied pressure, as described below.

7.1.1.1 If the waste will obviously yield no liquid when subjected to pressure filtration (i.e., is 100% solids) proceed to Section 7.1.3.

7.1.1.2 If the sample is liquid or multiphasic, liquid/solid separation to make a preliminary determination of percent solids is required. This involves the filtration device described in Section 4.3.2 and is outlined in Sections 7.1.1.3 through 7.1.1.9.

7.1.1.3 Pre-weigh the filter and the container that will receive the filtrate.

7.1.1.4 Assemble the filter holder and filter following the manufacturer's instructions. Place the filter on the support screen and secure.

7.1.1.5 Weigh out a subsample of the waste (100 gram minimum) and record the weight.

7.1.1.6 Allow slurries to stand to permit the solid phase to settle. Wastes that settle slowly may be centrifuged prior to filtration. Centrifugation is to be used only as an aid to filtration. If used, the liquid should be decanted and filtered followed by filtration of the solid portion of the waste through the same filtration system.

7.1.1.7 Quantitatively transfer the waste sample to the filter holder (liquid and solid phases). Spread the waste sample evenly over the surface of the filter. If filtration of the waste at 4 °C reduces the amount of expressed liquid over what would be expressed at room temperature then allow the sample to warm up to room temperature in the device before filtering.

NOTE: If waste material (>1% of original sample weight) has obviously adhered to the container used to transfer the sample to the filtration apparatus, determine the weight of this residue and subtract it from the sample weight determined in Section 7.1.1.5 to determine the weight of the waste sample that will be filtered.

Gradually apply vacuum or gentle pressure of 1-10 psi, until air or pressurizing gas moves through the filter. If this point is not reached under 10 psi, and if no additional liquid has passed through the filter in any 2 minute interval, slowly increase the pressure in 10 psi increments to a maximum of 50 psi. After each incremental increase of 10 psi, if the pressurizing gas has not moved through the filter, and if no additional liquid has passed through the filter in any 2 minute interval, proceed to the next 10 psi increment. When the pressurizing gas begins to move through the filter, or when liquid flow has ceased at 50 psi (i.e., filtration does not result in any additional filtrate within any 2 minute period), stop the filtration.

NOTE: Instantaneous application of high pressure can degrade the glass fiber filter and may cause premature plugging.

7.1.1.8 The material in the filter holder is defined as the solid phase of the waste, and the filtrate is defined as the liquid phase.

NOTE: Some wastes, such as oily wastes and some paint wastes, will obviously contain some material that appears to be a liquid. Even after applying vacuum or pressure filtration, as outlined in Section 7.1.1.7, this material may not filter. If this is the case, the material within the filtration device is defined as a solid. Do not replace the original filter with a fresh filter under any circumstances. Use only one filter.

7.1.1.9 Determine the weight of the liquid phase by subtracting the weight of the filtrate container (see Section 7.1.1.3) from the total weight of the filtrate-filled container. Determine the weight of the solid phase of the waste sample by subtracting the weight of the liquid phase from the weight of the total waste sample, as determined in Section 7.1.1.5 or 7.1.1.7.

Record the weight of the liquid and solid phases. Calculate the percent solids as follows:

$$\text{Percent solids} = \frac{\text{Weight of solid (Section 7.1.1.9)}}{\text{Total weight of waste (Section 7.1.1.5 or 7.1.1.7)}} \times 100$$

7.1.2 If the percent solids determined in Section 7.1.1.9 is equal to or greater than 0.5%, then proceed either to Section 7.1.3 to

determine whether the solid material requires particle size reduction or to Section 7.1.2.1 if it is noticed that a small amount of the filtrate is entrained in wetting of the filter. If the percent solids determined in Section 7.1.1.9 is less than 0.5%, then proceed to Section 7.2.9 if the nonvolatile TCLP is to be performed and to Section 7.3 with a fresh portion of the waste if the volatile TCLP is to be performed.

7.1.2.1 Remove the solid phase and filter from the filtration apparatus.

7.1.2.2 Dry the filter and solid phase at 100 ± 20 °C until two successive weighing yield the same value within ± 1%. Record the final weight.

NOTE: Caution should be taken to ensure that the subject solid will not flash upon heating. It is recommended that the drying oven be vented to a hood or other appropriate device.

7.1.2.3 Calculate the percent dry solids as follows: (Wt. of dry waste + filter) - tared wt. of filter

$$\text{Percent dry solids} = \frac{\text{(Wt. of dry waste + filter) - tared wt. of filter}}{\text{Initial wt. of waste (Section 7.1.1.5 or 7.1.1.7)}} \times 100$$

7.1.2.4 If the percent dry solids is less than 0.5%, then proceed to Section 7.2.9 if the nonvolatile TCLP is to be performed, and to Section 7.3 if the volatile TCLP is to be performed. If the percent dry solids is greater than or equal to 0.5%, and if the nonvolatile TCLP is to be performed, return to the beginning of this Section (7.1) and, with a fresh portion of waste, determine whether particle size reduction is necessary (Section 7.1.3) and determine the appropriate extraction fluid (Section 7.1.4). If only the volatile TCLP is to be performed, see the note in Section 7.1.4.

7.1.3 Determination of whether the waste requires particle size reduction (particle size is reduced during this step): Using the solid portion of the waste, evaluate the solid for particle size. Particle size reduction is required, unless the solid has a surface area per gram of material equal to or greater than 3.1 cm^2, or is smaller than 1 cm in its narrowest dimension (i.e., is capable of passing through a 9.5 mm (0.375 inch) standard sieve). If the surface area is smaller or the particle size larger than described above, prepare the solid portion of the waste for extraction by crushing, cutting, or grinding the waste to a surface area or particle size as described above. If the solids are prepared for organic volatiles extraction, special precautions must be taken (see Section 7.3.6).

NOTE: Surface area criteria are meant for filamentous (e.g., paper, cloth, and similar) waste materials. Actual measurement of surface area is not required, nor is it recommended. For materials that do not obviously meet

the criteria, sample specific methods would need to be developed and employed to measure the surface area. Such methodology is currently not available.

7.1.4 Determination of appropriate extraction fluid: If the solid content of the waste is greater than or equal to 0.5% and if the sample will be extracted for nonvolatile constituents (Section 7.2), determine the appropriate fluid (Section 5.7) for the nonvolatiles extraction as follows:

NOTE: TCLP extraction for volatile constituents uses only extraction fluid #1 (Section 5.7.1). Therefore, if TCLP extraction for nonvolatiles is not required, proceed to Section 7.3.

7.1.4.1 Weigh out a small subsample of the solid phase of the waste, reduce the solid (if necessary) to a particle size of approximately 1 mm in diameter or less, and transfer 5.0 grams of the solid phase of the waste to a 500 mL beaker or Erlenmeyer flask.

7.1.4.2 Add 96.5 mL of reagent water to the beaker, cover with a watchglass, and stir vigorously for 5 minutes using a magnetic stirrer. Measure and record the pH. If the pH is <5.0, use extraction fluid #1. Proceed to Section 7.2.

7.1.4.3 If the pH from Section 7.1.4.2 is >5.0, add 3.5 mL 1N HCl, slurry briefly, cover with a watchglass, heat to 50 °C, and hold at 50 °C for 10 minutes.

7.1.4.4 Let the solution cool to room temperature and record the pH. If the pH is <5.0, use extraction fluid #1. If the pH is >5.0, use extraction fluid #2. Proceed to Section 7.2.

7.1.5 If the aliquot of the waste used for the preliminary evaluation (Sections 7.1.1 - 7.1.4) was determined to be 100% solid at Section 7.1.1.1, then it can be used for the Section 7.2 extraction (assuming at least 100 grams remain), and the Section 7.3 extraction (assuming at least 25 grams remain). If the aliquot was subjected to the procedure in Section 7.1.1.7, then another aliquot shall be used for the volatile extraction procedure in Section 7.3. The aliquot of the waste subjected to the procedure in Section 7.1.1.7 might be appropriate for use for the Section 7.2 extraction if an adequate amount of solid (as determined by Section 7.1.1.9) was obtained. The amount of solid necessary is dependent upon whether a sufficient amount of extract will be produced to support the analyses. If an adequate amount of solid remains, proceed to Section 7.2.10 of the nonvolatile TCLP extraction.

7.2 Procedure When Volatiles are not Involved

A minimum sample size of 100 grams (solid and liquid phases) is recommend- ed. In some cases, a larger sample size may be appropriate, depending on the

solids content of the waste sample (percent solids, See Section 7.1.1), whether the initial liquid phase of the waste will be miscible with the aqueous extract of the solid, and whether inorganics, semivolatile organics, pesticides, and herbicides are all analytes of concern. Enough solids should be generated for extraction such that the volume of TCLP extract will be sufficient to support all of the analyses required. If the amount of extract generated by a single TCLP extraction will not be sufficient to perform all of the analyses, more than one extraction may be performed and the extracts from each combined and aliquoted for analysis.

7.2.1 If the waste will obviously yield no liquid when subjected to pressure filtration (i.e., is 100% solid, see Section 7.1.1), weigh out a subsample of the waste (100 gram minimum) and proceed to Section 7.2.9.

7.2.2 If the sample is liquid or multiphasic, liquid/solid separation is required. This involves the filtration device described in Section 4.3.2 and is outlined in Sections 7.2.3 to 7.2.8.

7.2.3 Pre-weigh the container that will receive the filtrate.

7.2.4 Assemble the filter holder and filter following the manufacturer's instructions. Place the filter on the support screen and secure. Acid wash the filter if evaluating the mobility of metals (see Section 4.4).

NOTE: Acid washed filters may be used for all nonvolatile extractions even when metals are not of concern.

7.2.5 Weigh out a subsample of the waste (100 gram minimum) and record the weight. If the waste contains <0.5% dry solids (Section 7.1.2), the liquid portion of the waste, after filtration, is defined as the TCLP extract. Therefore, enough of the sample should be filtered so that the amount of filtered liquid will support all of the analyses required of the TCLP extract. For wastes containing >0.5% dry solids (Sections 7.1.1 or 7.1.2), use the percent solids information obtained in Section 7.1.1 to determine the optimum sample size (100 gram minimum) for filtration. Enough solids should be generated by filtration to support the analyses to be performed on the TCLP extract.

7.2.6 Allow slurries to stand to permit the solid phase to settle. Wastes that settle slowly may be centrifuged prior to filtration. Use centrifugation only as an aid to filtration. If the waste is centrifuged, the liquid should be decanted and filtered followed by filtration of the solid portion of the waste through the same filtration system.

7.2.7 Quantitatively transfer the waste sample (liquid and solid phases) to the filter holder (see Section 4.3.2). Spread the waste sample evenly over the surface of the filter. If filtration of the waste at 4 °C reduces the amount of expressed liquid over what would be expressed at

room temperature, then allow the sample to warm up to room temperature in the device before filtering.

NOTE: If waste material (>1% of the original sample weight) has obviously adhered to the container used to transfer the sample to the filtration apparatus, determine the weight of this residue and subtract it from the sample weight determined in Section 7.2.5, to determine the weight of the waste sample that will be filtered.

Gradually apply vacuum or gentle pressure of 1-10 psi, until air or pressurizing gas moves through the filter. If this point is not reached under 10 psi, and if no additional liquid has passed through the filter in any 2 minute interval, slowly increase the pressure in 10 psi increments to a maximum of 50 psi. After each incremental increase of 10 psi, if the pressurizing gas has not moved through the filter, and if no additional liquid has passed through the filter in any 2 minute interval, proceed to the next 10 psi increment. When the pressurizing gas begins to move through the filter, or when the liquid flow has ceased at 50 psi (i.e., filtration does not result in any additional filtrate within a 2 minute period), stop the filtration.

NOTE: Instantaneous application of high pressure can degrade the glass fiber filter and may cause premature plugging.

7.2.8 The material in the filter holder is defined as the solid phase of the waste, and the filtrate is defined as the liquid phase. Weigh the filtrate. The liquid phase may now be either analyzed (See Section 7.2.12) or stored at 4 °C until time of analysis.

NOTE: Some wastes, such as oily wastes and some paint wastes, will obviously contain some material that appears to be a liquid. Even after applying vacuum or pressure filtration, as outlined in Section 7.2.7, this material may not filter. If this is the case, the material within the filtration device is defined as a solid and is carried through the extraction as a solid. Do not replace the original filter with a fresh filter under any circumstances. Use only one filter.

7.2.9 If the waste contains <0.5% dry solids (see Section 7.1.2), proceed to Section 7.2.13. If the waste contains >0.5% dry solids (see Section 7.1.1 or 7.1.2), and if particle size reduction of the solid was needed in Section 7.1.3, proceed to Section 7.2.10. If the waste as received passes a 9.5 mm sieve, quantitatively transfer the solid material into the extractor bottle along with the filter used to separate the initial liquid from the solid phase, and proceed to Section 7.2.11.

7.2.10 Prepare the solid portion of the waste for extraction by crushing, cutting, or grinding the waste to a surface area or particle size as described in Section 7.1.3. When the surface area or particle size has been appropriately altered, quantitatively transfer the solid

material into an extractor bottle. Include the filter used to separate the initial liquid from the solid phase.

NOTE: Sieving of the waste is not normally required. Surface area requirements are meant for filamentous (e.g., paper, cloth) and similar waste materials. Actual measurement of surface area is not recommended. If sieving is necessary, a Teflon coated sieve should be used to avoid contamination of the sample.

7.2.11 Determine the amount of extraction fluid to add to the extractor vessel as follows:

$$\text{Weight of extraction fluid} = \frac{20 \times \text{percent solids (Section 7.1.1)} \times \text{weight of waste filtered (Section 7.2.5 or 7.2.7)}}{100}$$

Slowly add this amount of appropriate extraction fluid (see Section 7.1.4) to the extractor vessel. Close the extractor bottle tightly (it is recommended that Teflon tape be used to ensure a tight seal), secure in rotary agitation device, and rotate at 30 ± 2 rpm for 18 ± 2 hours. Ambient temperature (i.e., temperature of room in which extraction takes place) shall be maintained at 23 ± 2 °C during the extraction period.

NOTE: As agitation continues, pressure may build up within the extractor bottle for some types of wastes (e.g., limed or calcium carbonate containing waste may evolve gases such as carbon dioxide). To relieve excess pressure, the extractor bottle may be periodically opened (e.g., after 15 minutes, 30 minutes, and 1 hour) and vented into a hood.

7.2.12 Following the 18 ± 2 hour extraction, separate the material in the extractor vessel into its component liquid and solid phases by filtering through a new glass fiber filter, as outlined in Section 7.2.7. For final filtration of the TCLP extract, the glass fiber filter may be changed, if necessary, to facilitate filtration. Filter(s) shall be acid-washed (see Section 4.4) if evaluating the mobility of metals.

7.2.13 Prepare the TCLP extract as follows:

7.2.13.1 If the waste contained no initial liquid phase, the filtered liquid material obtained from Section 7.2.12 is defined as the TCLP extract. Proceed to Section 7.2.14.

7.2.13.2 If compatible (e.g., multiple phases will not result on combination), combine the filtered liquid resulting from Section 7.2.12 with the initial liquid phase of the waste obtained in Section 7.2.7. This combined liquid is defined as the TCLP extract. Proceed to Section 7.2.14.

7.2.13.3 If the initial liquid phase of the waste, as obtained from Section 7.2.7, is not or may not be compatible with the filtered liquid resulting from Section 7.2.12, do not combine these liquids. Analyze these liquids, collectively defined as the TCLP extract, and combine the results mathematically, as described in Section 7.2.14.

7.2.14 Following collection of the TCLP extract, the pH of the extract should be recorded. Immediately aliquot and preserve the extract for analysis. Metals aliquots must be acidified with nitric acid to pH <2. If precipitation is observed upon addition of nitric acid to a small aliquot of the extract, then the remaining portion of the extract for metals analyses shall not be acidified and the extract shall be analyzed as soon as possible. All other aliquots must be stored under refrigeration (4 °C) until analyzed. The TCLP extract shall be prepared and analyzed according to appropriate analytical methods. TCLP extracts to be analyzed for metals shall be acid digested except in those instances where digestion causes loss of metallic analytes. If an analysis of the undigested extract shows that the concentration of any regulated metallic analyte exceeds the regulatory level, then the waste is hazardous and digestion of the extract is not necessary. However, data on undigested extracts alone cannot be used to demonstrate that the waste is not hazardous. If the individual phases are to be analyzed separately, determine the volume of the individual phases (to $\pm$ 0.5%), conduct the appropriate analyses, and combine the results mathematically by using a simple volume-weighted average:

$$\text{Final Analyte Concentration} = \frac{(V_1)(C_1) + (V_2)(C_2)}{V_1 + V_2}$$

where:

V_1 = The volume of the first phase (L).
C_1 = The concentration of the analyte of concern in the first phase (mg/L).
V_2 = The volume of the second phase (L).
C_2 = The concentration of the analyte of concern in the second phase (mg/L).

7.2.15 Compare the analyte concentrations in the TCLP extract with the levels identified in the appropriate regulations. Refer to Section 8.0 for quality assurance requirements.

7.3 Procedure When Volatiles are Involved

Use the ZHE device to obtain TCLP extract for analysis of volatile compounds only. Extract resulting from the use of the ZHE shall not be used to evaluate the mobility of nonvolatile analytes (e.g., metals, pesticides, etc.).

The ZHE device has approximately a 500 mL internal capacity. The ZHE can thus accommodate a maximum of 25 grams of solid (defined as that fraction of a

sample from which no additional liquid may be forced out by an applied pressure of 50 psi), due to the need to add an amount of extraction fluid equal to 20 times the weight of the solid phase.

Charge the ZHE with sample only once and do not open the device until the final extract (of the solid) has been collected. Repeated filling of the ZHE to obtain 25 grams of solid is not permitted.

Do not allow the waste, the initial liquid phase, or the extract to be exposed to the atmosphere for any more time than is absolutely necessary. Any manipulation of these materials should be done when cold (4 °C) to minimize loss of volatiles.

7.3.1 Pre-weigh the (evacuated) filtrate collection container (See Section 4.6) and set aside. If using a TEDLAR® bag, express all liquid from the ZHE device into the bag, whether for the initial or final liquid/solid separation, and take an aliquot from the liquid in the bag for analysis. The containers listed in Section 4.6 are recommended for use under the conditions stated in Sections 4.6.1 - 4.6.3.

7.3.2 Place the ZHE piston within the body of the ZHE (it may be helpful first to moisten the piston O-rings slightly with extraction fluid). Adjust the piston within the ZHE body to a height that will minimize the distance the piston will have to move once the ZHE is charged with sample (based upon sample size requirements determined from Section 7.3, Section 7.1.1 and/or 7.1.2). Secure the gas inlet/outlet flange (bottom flange) onto the ZHE body in accordance with the manufacturer's instructions. Secure the glass fiber filter between the support screens and set aside. Set liquid inlet/outlet flange (top flange) aside.

7.3.3 If the waste is 100% solid (see Section 7.1.1), weigh out a subsample (25 gram maximum) of the waste, record weight, and proceed to Section 7.3.5.

7.3.4 If the waste contains < 0.5% dry solids (Section 7.1.2), the liquid portion of waste, after filtration, is defined as the TCLP extract. Filter enough of the sample so that the amount of filtered liquid will support all of the volatile analyses required. For wastes containing $\geq$ 0.5% dry solids (Sections 7.1.1 and/or 7.1.2), use the percent solids information obtained in Section 7.1.1 to determine the optimum sample size to charge into the ZHE. The recommended sample size is as follows:

7.3.4.1 For wastes containing < 5% solids (see Section 7.1.1), weigh out a 500 gram subsample of waste and record the weight.

7.3.4.2 For wastes containing $\geq$ 5% solids (see Section 7.1.1), determine the amount of waste to charge into the ZHE as follows:

$$\text{Weight of waste to charge ZHE} = \frac{25}{\text{percent solids (Section 7.1.1)}} \times 100$$

Weigh out a subsample of the waste of the appropriate size and record the weight.

7.3.5 If particle size reduction of the solid portion of the waste was required in Section 7.1.3, proceed to Section 7.3.6. If particle size reduction was not required in Section 7.1.3, proceed to Section 7.3.7.

7.3.6 Prepare the waste for extraction by crushing, cutting, or grinding the solid portion of the waste to a surface area or particle size as described in Section 7.1.3. Wastes and appropriate reduction equipment should be refrigerated, if possible, to 4 °C prior to particle size reduction. The means used to effect particle size reduction must not generate heat in and of itself. If reduction of the solid phase of the waste is necessary, exposure of the waste to the atmosphere should be avoided to the extent possible.

NOTE: Sieving of the waste is not recommended due to the possibility that volatiles may be lost. The use of an appropriately graduated ruler is recommended as an acceptable alternative. Surface area requirements are meant for filamentous (e.g., paper, cloth) and similar waste materials. Actual measurement of surface area is not recommended.

When the surface area or particle size has been appropriately altered, proceed to Section 7.3.7.

7.3.7 Waste slurries need not be allowed to stand to permit the solid phase to settle. Do not centrifuge wastes prior to filtration.

7.3.8 Quantitatively transfer the entire sample (liquid and solid phases) quickly to the ZHE. Secure the filter and support screens onto the top flange of the device and secure the top flange to the ZHE body in accordance with the manufacturer's instructions. Tighten all ZHE fittings and place the device in the vertical position (gas inlet/outlet flange on the bottom). Do not attach the extract collection device to the top plate.

NOTE: If waste material (>1% of original sample weight) has obviously adhered to the container used to transfer the sample to the ZHE, determine the weight of this residue and subtract it from the sample weight determined in Section 7.3.4 to determine the weight of the waste sample that will be filtered.

Attach a gas line to the gas inlet/outlet valve (bottom flange) and, with the liquid inlet/outlet valve (top flange) open, begin applying gentle pressure of 1-10 psi (or more if necessary) to force all headspace

closure of the ZHE device into a hood. At the first appearance of liquid from the liquid inlet/outlet valve, quickly close the valve and discontinue pressure. If filtration of the waste at 4 °C reduces the amount of expressed liquid over what would be expressed at room tempera- ture, then allow the sample to warm up to room temperature in the device before filtering. If the waste is 100% solid (see Section 7.1.1), slowly increase the pressure to a maximum of 50 psi to force most of the headspace out of the device and proceed to Section 7.3.12.

7.3.9 Attach the evacuated pre-weighed filtrate collection container to the liquid inlet/outlet valve and open the valve. Begin applying gentle pressure of 1-10 psi to force the liquid phase of the sample into the filtrate collection container. If no additional liquid has passed through the filter in any 2 minute interval, slowly increase the pressure in 10 psi increments to a maximum of 50 psi. After each incremental increase of 10 psi, if no additional liquid has passed through the filter in any 2 minute interval, proceed to the next 10 psi increment. When liquid flow has ceased such that continued pressure filtration at 50 psi does not result in any additional filtrate within a 2 minute period, stop the filtration. Close the liquid inlet/outlet valve, discontinue pressure to the piston, and disconnect and weigh the filtrate collection container.

NOTE: Instantaneous application of high pressure can degrade the glass fiber filter and may cause premature plugging.

7.3.10 The material in the ZHE is defined as the solid phase of the waste and the filtrate is defined as the liquid phase.

NOTE: Some wastes, such as oily wastes and some paint wastes, will obviously contain some material that appears to be a liquid. Even after applying pressure filtration, this material will not filter. If this is the case, the material within the filtration device is defined as a solid and is carried through the TCLP extraction as a solid.

If the original waste contained <0.5% dry solids (see Section 7.1.2), this filtrate is defined as the TCLP extract and is analyzed directly. Proceed to Section 7.3.15.

7.3.11 The liquid phase may now be either analyzed immediately (See Sections 7.3.13 through 7.3.15) or stored at 4 °C under minimal headspace conditions until time of analysis. Determine the weight of extraction fluid #1 to add to the ZHE as follows:

$$\text{Weight of extraction fluid} = \frac{20 \times \text{percent solids (Section 7.1.1)} \times \text{weight of waste filtered (Section 7.3.4 or 7.3.8)}}{100}$$

7.3.12 The following Sections detail how to add the appropriate amount of extraction fluid to the solid material within the ZHE and agitation of the ZHE vessel. Extraction fluid #1 is used in all cases (See Section 5.7).

7.3.12.1 With the ZHE in the vertical position, attach a line from the extraction fluid reservoir to the liquid in- let/outlet valve. The line used shall contain fresh extraction fluid and should be preflushed with fluid to eliminate any air pockets in the line. Release gas pressure on the ZHE piston (from the gas inlet/outlet valve), open the liquid inlet/outlet valve, and begin transferring extraction fluid (by pumping or similar means) into the ZHE. Continue pumping extraction fluid into the ZHE until the appropriate amount of fluid has been introduced into the device.

7.3.12.2 After the extraction fluid has been added, immediately close the liquid inlet/outlet valve and disconnect the extraction fluid line. Check the ZHE to ensure that all valves are in their closed positions. Manually rotate the device in an end-over-end fashion 2 or 3 times. Reposition the ZHE in the vertical position with the liquid inlet/outlet valve on top. Pressurize the ZHE to 5-10 psi (if necessary) and slowly open the liquid inlet/outlet valve to bleed out any headspace (into a hood) that may have been introduced due to the addition of extraction fluid. This bleeding shall be done quickly and shall be stopped at the first appearance of liquid from the valve. Re-pressurize the ZHE with 5-10 psi and check all ZHE fittings to ensure that they are closed.

7.3.12.3 Place the ZHE in the rotary agitation appara- tus (if it is not already there) and rotate at 30 $\pm$ 2 rpm for 18 $\pm$ 2 hours. Ambient temperature (i.e., temperature of room in which extraction occurs) shall be maintained at 23 $\pm$ 2 °C during agita- tion.

7.3.13 Following the 18 $\pm$ 2 hour agitation period, check the pressure behind the ZHE piston by quickly opening and closing the gas inlet/outlet valve and noting the escape of gas. If the pressure has not been maintained (i.e., no gas release observed), the device is leaking. Check the ZHE for leaking as specified in Section 4.2.1, and perform the extraction again with a new sample of waste. If the pressure within the device has been maintained, the material in the extractor vessel is once again separated into its component liquid and solid phases. If the waste contained an initial liquid phase, the liquid may be filtered directly into the same filtrate collection container (i.e., TEDLAR® bag) holding the initial liquid phase of the waste. A separate filtrate collection container must be used if combining would create multiple phases, or there is not enough volume left within the filtrate collection container. Filter through the glass fiber filter, using the ZHE device as discussed in Section 7.3.9. All extract shall be filtered and collected if the

TEDLAR® bag is used, if the extract is multiphasic, or if the waste contained an initial liquid phase (see Sections 4.6 and 7.3.1).

NOTE: An in-line glass fiber filter may be used to filter the material within the ZHE if it is suspected that the glass fiber filter has been ruptured.

7.3.14 If the original waste contained no initial liquid phase, the filtered liquid material obtained from Section 7.3.13 is defined as the TCLP extract. If the waste contained an initial liquid phase, the filtered liquid material obtained from Section 7.3.13 and the initial liquid phase (Section 7.3.9) are collectively defined as the TCLP extract.

7.3.15 Following collection of the TCLP extract, immediately prepare the extract for analysis and store with minimal headspace at 4 °C until analyzed. Analyze the TCLP extract according to the appropriate analytical methods. If the individual phases are to be analyzed separately (i.e., are not miscible), determine the volume of the individual phases (to 0.5%), conduct the appropriate analyses, and combine the results mathematically by using a simple volume-weighted average:

$$\text{Final Analyte Concentration} = \frac{(V_1)(C_1) + (V_2)(C_2)}{V_1 + V_2}$$

where:

V_1 = The volume of the first phases (L).
C_1 = The concentration of the analyte of concern in the first phase (mg/L).
V_2 = The volume of the second phase (L).
C_2 = The concentration of the analyte of concern in the second phase (mg/L).

7.3.16 Compare the analyte concentrations in the TCLP extract with the levels identified in the appropriate regulations. Refer to Section 8.0 for quality assurance requirements.

8.1 QUALITY ASSURANCE

8.2 A minimum of one blank (using the same extraction fluid as used for the samples) must be analyzed for every 20 extractions that have been conducted in an extraction vessel.

8.3 A matrix spike shall be performed for each waste type (e.g., wastewater treatment sludge, contaminated soil, etc.) unless the result exceeds the regulatory level and the data are being used solely to demonstrate that the waste property exceeds the regulatory level. A minimum of one matrix spike must be analyzed for each analytical batch. As a minimum, follow the matrix spike addition guidance provided in each analytical method.

8.3.1 Matrix spikes are to be added after filtration of the TCLP extract and before preservation. Matrix spikes should not be added prior to TCLP extraction of the sample.

8.3.2 In most cases, matrix spikes should be added at a concentration equivalent to the corresponding regulatory level. If the analyte concentration is less than one half the regulatory level, the spike concentration may be as low as one half of the analyte concentra- tion, but may not be not less than five times the method detection limit. In order to avoid differences in matrix effects, the matrix spikes must be added to the same nominal volume of TCLP extract as that which was analyzed for the unspiked sample.

8.3.3 The purpose of the matrix spike is to monitor the performance of the analytical methods used, and to determine whether matrix interferences exist. Use of other internal calibration methods, modification of the analytical methods, or use of alternate analytical methods may be needed to accurately measure the analyte concentration in the TCLP extract when the recovery of the matrix spike is below the expected analytical method performance.

8.3.4 Matrix spike recoveries are calculated by the following formula:

$$\%R\ (\%Recovery) = 100\ (X_s - X_u)/K$$

where:
X_s = measured value for the spiked sample,
X_u = measured value for the unspiked sample, and
K = known value of the spike in the sample.

8.4 All quality control measures described in the appropriate analytical methods shall be followed.

8.5 The use of internal calibration quantitation methods shall be employed for a metallic contaminant if: (1) Recovery of the contaminant from the TCLP extract is not at least 50% and the concentration does not exceed the regulatory level, and (2) The concentration of the contaminant measured in the extract is within 20% of the appropriate regulatory level.

8.4.1. The method of standard additions shall be employed as the internal calibration quantitation method for each metallic contaminant.

8.4.2 The method of standard additions requires preparing calibration standards in the sample matrix rather than reagent water or blank solution. It requires taking four identical aliquots of the solution and adding known amounts of standard to three of these aliquots. The forth aliquot is the unknown. Preferably, the first addition should be prepared so that the resulting concentration is approximately 50% of the expected concentration of the sample. The second and third additions should be prepared so that the concentrations are approximately 100% and

150% of the expected concentration of the sample. All four aliquots are maintained at the same final volume by adding reagent water or a blank solution, and may need dilution adjustment to maintain the signals in the linear range of the instrument technique. All four aliquots are analyzed.

8.4.3 Prepare a plot, or subject data to linear regression, of instrument signals or external-calibration-derived concentrations as the dependant variable (y-axis) versus concentrations of the additions of standard as the independent variable (x-axis). Solve for the intercept of the abscissa (the independent variable, x-axis) which is the concentration in the unknown.

8.4.4 Alternately, subtract the instrumental signal or external- calibration-derived concentration of the unknown (unspiked) sample from the instrumental signals or external-calibration-derived concentrations of the standard additions. Plot or subject to linear regression of the corrected instrument signals or external-calibration-derived concentra- tions as the dependant variable versus the independent variable. Derive concentrations for unknowns using the internal calibration curve as if it were an external calibration curve.

8.5 Samples must undergo TCLP extraction within the following time periods:

SAMPLE MAXIMUM HOLDING TIMES [DAYS]

	From: Field collection To: TCLP extraction	From: TCLP extraction To: Preparative extraction	From: Preparative extraction To: Determinative analysis	Total elapsed time
Volatiles	14	NA	14	28
Semi-volatiles	14	7	40	61
Mercury	28	NA	28	56
Metals, except mercury	180	NA	180	360

NA = Not applicable

If sample holding times are exceeded, the values obtained will be considered minimal concentrations. Exceeding the holding time is not acceptable in establishing that a waste does not exceed the regulatory level. Exceeding the holding time will not invalidate characterization if the waste exceeds the regulatory level.

9.1 METHOD PERFORMANCE

9.2 Ruggedness. Two ruggedness studies have been performed to determine the effect of various perturbations on specific elements of the TCLP protocol. Ruggedness testing determines the sensitivity of small procedural variations which might be expected to occur during routine laboratory application.

9.2.1 Metals - The following conditions were used when leaching a waste for metals analysis:

Varying Conditions	
Liquid/Solid ratio	19:1 vs. 21:1
Extraction time	16 hours vs. 18 hours
Headspace	20% vs. 60%
Buffer #2 acidity	190 meq vs. 210 meq
Acid-washed filters	yes vs. no
Filter type	0.7 µm glass fiber vs. 0.45 µm vs. polycarbonate
Bottle type	borosilicate vs. flint glass

Of the seven method variations examined, acidity of the extraction fluid had the greatest impact on the results. Four of 13 metals from an API separator sludge/electroplating waste (API/EW) mixture and two of three metals from an ammonia lime still bottom waste were extracted at higher levels by the more acidic buffer. Because of the sensitivity to pH changes, the method requires that the extraction fluids be prepared so that the final pH is within $\pm$ 0.05 units as specified.

9.2.2 Volatile Organic Compounds - The following conditions were used when leaching a waste for VOC analysis:

Varying Conditions	
Liquid/Solid ratio	19:1 vs. 21:1
Headspace	0% vs. 5%
Buffer #1 acidity	60 meq vs. 80 meq
Method of storing extract	Syringe vs. Tedlar® bag
Aliquotting	yes vs. no
Pressure behind piston	0 psi vs. 20 psi

None of the parameters had a significant effect on the results of the ruggedness test.

9.3 Precision. Many TCLP precision (reproducibility) studies have been performed, and have shown that, in general, the precision of the TCLP is comparable to or exceeds that of the EP toxicity test and that method precision is adequate. One of the more significant contributions to poor precision appears to be related to sample homogeneity and inter-laboratory variation (due to the nature of waste materials).

9.3.1 Metals - The results of a multi-laboratory study are shown in Table 6, and indicate that a single analysis of a waste may not be adequate for waste characterization and identification requirements.

9.3.2 Semi-Volatile Organic Compounds - The results of two studies are shown in Tables 7 and 8. Single laboratory precision was excellent with greater than 90 percent of the results exhibiting an RSD less than 25 percent. Over 85 percent of all individual compounds in the multi-laboratory study fell in the RSD range of 20 - 120 percent. Both studies concluded that the TCLP provides adequate precision. It was also determined that the high acetate content of the extraction fluid did not present problems (i.e., column degradation of the gas chromatograph) for the analytical conditions used.

9.3.3 Volatile Organic Compounds - Eleven laboratories participated in a collaborative study of the use of the ZHE with two waste types which were fortified with a mixture of VOCs. The results of the collaborative study are shown in Table 9. Precision results for VOCs tend to occur over a considerable range. However, the range and mean RSD compared very closely to the same collaborative study metals results in Table 6. Blackburn and Show concluded that at the 95% level of signifi- cance: 1) recoveries among laboratories were statistically similar, 2) recoveries did not vary significantly between the two sample types, and 3) each laboratory showed the same pattern of recovery for each of the two samples.

Toxicity Characteristic Leaching Procedure

METHOD 1311

TOXICITY CHARACTERISTIC LEACHING PROCEDURE

1.1 SCOPE AND APPLICATION

1.2 The TCLP is designed to determine the mobility of both organic and inorganic analytes present in liquid, solid, and multiphasic wastes.

1.3 If a total analysis of the waste demonstrates that individual analytes are not present in the waste, or that they are present but at such low concentrations that the appropriate regulatory levels could not possibly be exceeded, the TCLP need not be run.

1.4 If an analysis of any one of the liquid fractions of the TCLP extract indicates that a regulated compound is present at such high concentra- tions that, even after accounting for dilution from the other fractions of the extract, the concentration would be above the regulatory level for that compound, then the waste is hazardous and it is not necessary to analyze the remaining fractions of the extract.

1.5 If an analysis of extract obtained using a bottle extractor shows that the concentration of any regulated volatile analyte exceeds the regulatory level for that compound, then the waste is hazardous and extraction using the ZHE is not necessary. However, extract from a bottle extractor cannot be used to demonstrate that the concentration of volatile compounds is below the regulatory level.

2.1 SUMMARY OF METHOD

2.2 For liquid wastes (i.e., those containing less than 0.5% dry solid material), the waste, after filtration through a 0.6 to 0.8 µm glass fiber filter, is defined as the TCLP extract.

2.3 For wastes containing greater than or equal to 0.5% solids, the liquid, if any, is separated from the solid phase and stored for later analysis; the particle size of the solid phase is reduced, if necessary. The solid phase is extracted with an amount of extraction fluid equal to 20 times the weight of the solid phase. The extraction fluid employed is a function of the alkalinity of the solid phase of the waste. A special extractor vessel is used when testing for volatile analytes (see Table 1 for a list of volatile compounds). Following extraction, the liquid extract is separated from the solid phase by filtration through a 0.6 to 0.8 µm glass fiber filter.

2.4 If compatible (i.e., multiple phases will not form on combination), the initial liquid phase of the waste is added to the liquid extract, and these are analyzed together. If incompatible, the liquids are analyzed separately and the results are mathematically combined to yield a volume-weighted average concentration.

3.1 INTERFERENCES

3.2 Potential interferences that may be encountered during analysis are discussed in the individual analytical methods.

4.1 APPARATUS AND MATERIALS

4.2 Agitation apparatus: The agitation apparatus must be capable of rotating the extraction vessel in an end-over-end fashion (see Figure 1) at 30 ± 2 rpm. Suitable devices known to EPA are identified in Table 2.

4.3 Extraction Vessels

4.3.1 Zero-Headspace Extraction Vessel (ZHE). This device is for use only when the waste is being tested for the mobility of volatile analytes (i.e., those listed in Table 1). The ZHE (depicted in Figure 2) allows for liquid/solid separation within the device, and effectively precludes headspace. This type of vessel allows for initial liquid/solid separation, extraction, and final extract filtration without opening the vessel (see Section 4.3.1). The vessels shall have an internal volume of 500-600 mL, and be equipped to accommodate a 90-110 mm filter. The devices contain VITON®[1] O-rings which should be replaced frequently. Suitable ZHE devices known to EPA are identified in Table 3.

For the ZHE to be acceptable for use, the piston within the ZHE should be able to be moved with approximately 15 psi or less. If it takes more pressure to move the piston, the O-rings in the device should be replaced. If this does not solve the problem, the ZHE is unacceptable for TCLP analyses and the manufacturer should be contacted.

The ZHE should be checked for leaks after every extraction. If the device contains a built-in pressure gauge, pressurize the device to 50 psi, allow it to stand unattended for 1 hour, and recheck the pressure. If the device does not have a built-in pressure gauge, pressurize the device to 50 psi, submerge it in water, and check for the presence of air bubbles escaping from any of the fittings. If pressure is lost, check all fittings and inspect and replace O-rings, if necessary. Retest the device. If leakage problems cannot be solved, the manufacturer should be contacted.

Some ZHEs use gas pressure to actuate the ZHE piston, while others use mechanical pressure (see Table 3). Whereas the volatiles procedure (see Section 7.3) refers to pounds per square inch (psi), for the mechanically actuated piston, the pressure applied is measured in torque-inch-pounds. Refer to the manufacturer's instructions as to the proper conversion.

[1] VITON® is a trademark of Du Pont.

4.3.2 Bottle Extraction Vessel. When the waste is being evaluated using the nonvolatile extraction, a jar with sufficient capacity to hold the sample and the extraction fluid is needed. Headspace is allowed in this vessel.

The extraction bottles may be constructed from various materials, depending on the analytes to be analyzed and the nature of the waste (see Section 4.3.3). It is recommended that borosilicate glass bottles be used instead of other types of glass, especially when inorganics are of concern. Plastic bottles, other than polytetrafluoroethylene, shall not be used if organics are to be investigated. Bottles are available from a number of laboratory suppliers. When this type of extraction vessel is used, the filtration device discussed in Section 4.3.2 is used for initial liquid/solid separation and final extract filtration.

4.4 Filtration Devices: It is recommended that all filtrations be performed in a hood.

4.4.1 Zero-Headspace Extractor Vessel (ZHE): When the waste is evaluated for volatiles, the zero-headspace extraction vessel described in Section 4.2.1 is used for filtration. The device shall be capable of supporting and keeping in place the glass fiber filter and be able to withstand the pressure needed to accomplish separation (50 psi).

NOTE: When it is suspected that the glass fiber filter has been ruptured, an in-line glass fiber filter may be used to filter the material within the ZHE.

4.4.2 Filter Holder: When the waste is evaluated for other than volatile analytes, any filter holder capable of supporting a glass fiber filter and able to withstand the pressure needed to accomplish separation may be used. Suitable filter holders range from simple vacuum units to relatively complex systems capable of exerting pressures of up to 50 psi or more. The type of filter holder used depends on the properties of the material to be filtered (see Section 4.3.3). These devices shall have a minimum internal volume of 300 mL and be equipped to accommodate a minimum filter size of 47 mm (filter holders having an internal capacity of 1.5 L or greater, and equipped to accommodate a 142 mm diameter filter, are recommended). Vacuum filtration can only be used for wastes with low solids content (<10%) and for highly granular, liquid-containing wastes. All other types of wastes should be filtered using positive pressure filtration. Suitable filter holders known to EPA are shown in Table 4.

4.4.3 Materials of Construction: Extraction vessels and filtration devices shall be made of inert materials which will not leach or absorb waste components. Glass, polytetrafluoroethylene (PTFE), or type 316 stainless steel equipment may be used when evaluating the mobility of both organic and inorganic components. Devices made of high density polyethylene (HDPE), polypropylene (PP), or polyvinyl chloride (PVC) may be used only when evaluating the mobility of metals. Borosili-

Pyrex glass bottles are recommended for use over other types of glass bottles, especially when inorganics are analytes of concern.

4.5 Filters: Filters shall be made of borosilicate glass fiber, shall contain no binder materials, and shall have an effective pore size of 0.6 to 0.8 µm, or equivalent. Filters known to EPA which meet these specifications are identified in Table 5. Pre-filters must not be used. When evaluating the mobility of metals, filters shall be acid-washed prior to use by rinsing with 1N nitric acid followed by three consecutive rinses with deionized distilled water (a minimum of 1 L per rinse is recommended). Glass fiber filters are fragile and should be handled with care.

4.5 pH Meters: The meter should be accurate to ± 0.05 units at 25 °C.

4.6 ZHE Extract Collection Devices: TEDLAR®[2] bags or glass, stainless steel or PTFE gas-tight syringes are used to collect the initial liquid phase and the final extract of the waste when using the ZHE device. The devices listed are recommended for use under the following conditions:

4.6.1 If a waste contains an aqueous liquid phase or if a waste does not contain a significant amount of nonaqueous liquid (i.e., <1% of total waste), the TEDLAR® bag or a 600 mL syringe should be used to collect and combine the initial liquid and solid extract.

4.6.2 If a waste contains a significant amount of nonaqueous liquid in the initial liquid phase (i.e., >1% of total waste), the syringe or the TEDLAR® bag may be used for both the initial solid/liquid separation and the final extract filtration. However, analysts should use one or the other, not both.

4.6.3 If the waste contains no initial liquid phase (is 100% solid) or has no significant solid phase (is 100% liquid), either the TEDLAR® bag or the syringe may be used. If the syringe is used, discard the first 5 mL of liquid expressed from the device. The remaining aliquots are used for analysis.

4.7 ZHE Extraction Fluid Transfer Devices: Any device capable of transferring the extraction fluid into the ZHE without changing the nature of the extraction fluid is acceptable (e.g., a positive displacement or peristaltic pump, a gas tight syringe, pressure filtration unit (see Section 4.3.2), or other ZHE device).

4.8 Laboratory Balance: Any laboratory balance accurate to within ± 0.01 grams may be used (all weight measurements are to be within ± 0.1 grams).

4.9 Beaker or Erlenmeyer flask, glass, 500 mL.

---

[2] TEDLAR® is a registered trademark of Du Pont.

4.10 Watchglass, appropriate diameter to cover beaker or Erlenmeyer flask.

4.11 Magnetic stirrer.

5.1 REAGENTS

5.2 Reagent grade chemicals shall be used in all tests. Unless otherwise indicated, it is intended that all reagents shall conform to the specifications of the Committee on Analytical Reagents of the American Chemical Society, where such specifications are available. Other grades may be used, provided it is first ascertained that the reagent is of sufficiently high purity to permit its use without lessening the accuracy of the determination.

5.3 Reagent Water. Reagent water is defined as water in which an interferant is not observed at or above the method's detection limit of the analyte(s) of interest. For nonvolatile extractions, ASTM Type II water or equivalent meets the definition of reagent water. For volatile extractions, it is recommended that reagent water be generated by any of the following methods. Reagent water should be monitored periodically for impurities.

5.3.1 Reagent water for volatile extractions may be generated by passing tap water through a carbon filter bed containing about 500 grams of activated carbon (Calgon Corp., Filtrasorb-300 or equivalent).

5.3.2 A water purification system (Millipore Super-Q or equivalent) may also be used to generate reagent water for volatile extractions.

5.3.3 Reagent water for volatile extractions may also be prepared by boiling water for 15 minutes. Subsequently, while maintaining the water temperature at 90 $\pm$ 5 degrees C, bubble a contaminant-free inert gas (e.g. nitrogen) through the water for 1 hour. While still hot, transfer the water to a narrow mouth screw-cap bottle under zero-headspace and seal with a Teflon-lined septum and cap.

5.4 Hydrochloric acid (1N), HCl, made from ACS reagent grade.

5.5 Nitric acid (1N), HNO_3, made from ACS reagent grade.

5.6 Sodium hydroxide (1N), NaOH, made from ACS reagent grade.

5.7 Glacial acetic acid, CH_3CH_2OOH, ACS reagent grade.

5.8 Extraction fluid.

5.8.1 Extraction fluid # 1: Add 5.7 mL glacial CH_3CH_2OOH to 500 mL of reagent water (See Section 5.2), add 64.3 mL of 1N NaOH, and dilute to a volume of 1 liter. When correctly prepared, the pH of this fluid will be 4.93 $\pm$ 0.05.

5.8.2 Extraction fluid # 2: Dilute 5.7 mL glacial CH_3CH_2OOH with reagent water (See Section 5.2) to a volume of 1 liter. When correctly prepared, the pH of this fluid will be 2.88 $\pm$ 0.05.

NOTE: These extraction fluids should be monitored frequently for impurities. The pH should be checked prior to use to ensure that these fluids are made up accurately. If impurities are found or the pH is not within the above specifications, the fluid shall be discarded and fresh extraction fluid prepared.

5.9 Analytical standards shall be prepared according to the appropriate analytical method.

6.1 SAMPLE COLLECTION, PRESERVATION, AND HANDLING

6.2 All samples shall be collected using an appropriate sampling plan.

6.3 The TCLP may place requirements on the minimal size of the field sample, depending upon the physical state or states of the waste and the analytes of concern. An aliquot is needed for preliminary evaluation of which extraction fluid is to be used for the nonvolatile analyte extraction procedure. Another aliquot may be needed to actually conduct the nonvolatile extraction (see Section 1.4 concerning the use of this extract for volatile organics). If volatile organics are of concern, another aliquot may be needed. Quality control measures may require additional aliquots. Further, it is always wise to collect more sample just in case something goes wrong with the initial attempt to conduct the test.

6.3 Preservatives shall not be added to samples before extraction.

6.4 Samples may be refrigerated unless refrigeration results in irreversible physical change to the waste. If precipitation occurs, the entire sample (including precipitate) should be extracted.

6.5 When the waste is to be evaluated for volatile analytes, care shall be taken to minimize the loss of volatiles. Samples shall be collected and stored in a manner intended to prevent the loss of volatile analytes (e.g., samples should be collected in Teflon-lined septum capped vials and stored at 4 °C. Samples should be opened only immediately prior to extraction).

6.6 TCLP extracts should be prepared for analysis and analyzed as soon as possible following extraction. Extracts or portions of extracts for metallic analyte determinations must be acidified with nitric acid to a pH < 2, unless precipitation occurs (see Section 7.2.14 if precipitation occurs). Extracts should be preserved for other analytes according to the guidance given in the individual analysis methods. Extracts or portions of extracts for organic analyte determinations shall not be allowed to come into contact with the atmosphere (i.e., no headspace) to prevent losses. See Section 8.0 (QA requirements) for acceptable sample and extract holding times.

7.2 Preliminary Evaluations

Perform preliminary TCLP evaluations on a minimum 100 gram aliquot of waste. This aliquot may not actually undergo TCLP extraction. These preliminary evaluations include: (1) determination of the percent solids (Section 7.1.1);
(2) determination of whether the waste contains insignificant solids and is, therefore, its own extract after filtration (Section 7.1.2); (3) determination of whether the solid portion of the waste requires particle size reduction (Section 7.1.3); and (4) determination of which of the two extraction fluids are to be used for the nonvolatile TCLP extraction of the waste (Section 7.1.4).

7.1.1 Preliminary determination of percent solids: Percent solids is defined as that fraction of a waste sample (as a percentage of the total sample) from which no liquid may be forced out by an applied pressure, as described below.

7.1.1.1 If the waste will obviously yield no liquid when subjected to pressure filtration (i.e., is 100% solids) proceed to Section 7.1.3.

7.1.1.2 If the sample is liquid or multiphasic, liquid/solid separation to make a preliminary determination of percent solids is required. This involves the filtration device described in Section 4.3.2 and is outlined in Sections 7.1.1.3 through 7.1.1.9.

7.1.1.3 Pre-weigh the filter and the container that will receive the filtrate.

7.1.1.4 Assemble the filter holder and filter following the manufacturer's instructions. Place the filter on the support screen and secure.

7.1.1.5 Weigh out a subsample of the waste (100 gram minimum) and record the weight.

7.1.1.6 Allow slurries to stand to permit the solid phase to settle. Wastes that settle slowly may be centrifuged prior to filtration. Centrifugation is to be used only as an aid to filtration. If used, the liquid should be decanted and filtered followed by filtration of the solid portion of the waste through the same filtration system.

7.1.1.7 Quantitatively transfer the waste sample to the filter holder (liquid and solid phases). Spread the waste sample evenly over the surface of the filter. If filtration of the waste at 4 °C reduces the amount of expressed liquid over what would be expressed at room temperature then allow the sample to warm up to room temperature in the device before filtering.

NOTE: If waste material (>1% of original sample weight) has obviously adhered to the container used to transfer the sample to the filtration apparatus, determine the weight of this residue and subtract it from the sample weight determined in Section 7.1.1.5 to determine the weight of the waste sample that will be filtered.

Gradually apply vacuum or gentle pressure of 1-10 psi, until air or pressurizing gas moves through the filter. If this point is not reached under 10 psi, and if no additional liquid has passed through the filter in any 2 minute interval, slowly increase the pressure in 10 psi increments to a maximum of 50 psi. After each incremental increase of 10 psi, if the pressurizing gas has not moved through the filter, and if no additional liquid has passed through the filter in any 2 minute interval, proceed to the next 10 psi increment. When the pressurizing gas begins to move through the filter, or when liquid flow has ceased at 50 psi (i.e., filtration does not result in any additional filtrate within any 2 minute period), stop the filtration.

NOTE: Instantaneous application of high pressure can degrade the glass fiber filter and may cause premature plugging.

7.1.1.8 The material in the filter holder is defined as the solid phase of the waste, and the filtrate is defined as the liquid phase.

NOTE: Some wastes, such as oily wastes and some paint wastes, will obviously contain some material that appears to be a liquid. Even after applying vacuum or pressure filtration, as outlined in Section 7.1.1.7, this material may not filter. If this is the case, the material within the filtration device is defined as a solid. Do not replace the original filter with a fresh filter under any circumstances. Use only one filter.

7.1.1.9 Determine the weight of the liquid phase by subtracting the weight of the filtrate container (see Section 7.1.1.3) from the total weight of the filtrate-filled container. Determine the weight of the solid phase of the waste sample by subtracting the weight of the liquid phase from the weight of the total waste sample, as determined in Section 7.1.1.5 or 7.1.1.7.

Record the weight of the liquid and solid phases. Calculate the percent solids as follows:

$$\text{Percent solids} = \frac{\text{Weight of solid (Section 7.1.1.9)}}{\text{Total weight of waste (Section 7.1.1.5 or 7.1.1.7)}} \times 100$$

7.1.2 If the percent solids determined in Section 7.1.1.9 is equal to or greater than 0.5%, then proceed either to Section 7.1.3 to

determine whether the solid material requires particle size reduction or to Section 7.1.2.1 if it is noticed that a small amount of the filtrate is entrained in wetting of the filter. If the percent solids determined in Section 7.1.1.9 is less than 0.5%, then proceed to Section 7.2.9 if the nonvolatile TCLP is to be performed and to Section 7.3 with a fresh portion of the waste if the volatile TCLP is to be performed.

7.1.2.1 Remove the solid phase and filter from the filtration apparatus.

7.1.2.2 Dry the filter and solid phase at 100 ± 20 °C until two successive weighing yield the same value within ± 1%. Record the final weight.

NOTE: Caution should be taken to ensure that the subject solid will not flash upon heating. It is recommended that the drying oven be vented to a hood or other appropriate device.

7.1.2.3 Calculate the percent dry solids as follows: (Wt. of dry waste + filter) - tared wt. of filter

$$\text{Percent dry solids} = \frac{\text{(Wt. of dry waste + filter) - tared wt. of filter}}{\text{Initial wt. of waste (Section 7.1.1.5 or 7.1.1.7)}} \times 100$$

7.1.2.4 If the percent dry solids is less than 0.5%, then proceed to Section 7.2.9 if the nonvolatile TCLP is to be performed, and to Section 7.3 if the volatile TCLP is to be performed. If the percent dry solids is greater than or equal to 0.5%, and if the nonvolatile TCLP is to be performed, return to the beginning of this Section (7.1) and, with a fresh portion of waste, determine whether particle size reduction is necessary (Section 7.1.3) and determine the appropriate extraction fluid (Section 7.1.4). If only the volatile TCLP is to be performed, see the note in Section 7.1.4.

7.1.3 Determination of whether the waste requires particle size reduction (particle size is reduced during this step): Using the solid portion of the waste, evaluate the solid for particle size. Particle size reduction is required, unless the solid has a surface area per gram of material equal to or greater than 3.1 cm^2, or is smaller than 1 cm in its narrowest dimension (i.e., is capable of passing through a 9.5 mm (0.375 inch) standard sieve). If the surface area is smaller or the particle size larger than described above, prepare the solid portion of the waste for extraction by crushing, cutting, or grinding the waste to a surface area or particle size as described above. If the solids are prepared for organic volatiles extraction, special precautions must be taken (see Section 7.3.6).

NOTE: Surface area criteria are meant for filamentous (e.g., paper, cloth, and similar) waste materials. Actual measurement of surface area is not required, nor is it recommended. For materials that do not obviously meet

the criteria, sample specific methods would need to be developed and employed to measure the surface area. Such methodology is currently not available.

7.1.4 Determination of appropriate extraction fluid: If the solid content of the waste is greater than or equal to 0.5% and if the sample will be extracted for nonvolatile constituents (Section 7.2), determine the appropriate fluid (Section 5.7) for the nonvolatiles extraction as follows:

NOTE: TCLP extraction for volatile constituents uses only extraction fluid #1 (Section 5.7.1). Therefore, if TCLP extraction for nonvolatiles is not required, proceed to Section 7.3.

7.1.4.1 Weigh out a small subsample of the solid phase of the waste, reduce the solid (if necessary) to a particle size of approximately 1 mm in diameter or less, and transfer 5.0 grams of the solid phase of the waste to a 500 mL beaker or Erlenmeyer flask.

7.1.4.2 Add 96.5 mL of reagent water to the beaker, cover with a watchglass, and stir vigorously for 5 minutes using a magnetic stirrer. Measure and record the pH. If the pH is <5.0, use extraction fluid #1. Proceed to Section 7.2.

7.1.4.3 If the pH from Section 7.1.4.2 is >5.0, add 3.5 mL 1N HCl, slurry briefly, cover with a watchglass, heat to 50 °C, and hold at 50 °C for 10 minutes.

7.1.4.4 Let the solution cool to room temperature and record the pH. If the pH is <5.0, use extraction fluid #1. If the pH is >5.0, use extraction fluid #2. Proceed to Section 7.2.

7.1.5 If the aliquot of the waste used for the preliminary evaluation (Sections 7.1.1 - 7.1.4) was determined to be 100% solid at Section 7.1.1.1, then it can be used for the Section 7.2 extraction (assuming at least 100 grams remain), and the Section 7.3 extraction (assuming at least 25 grams remain). If the aliquot was subjected to the procedure in Section 7.1.1.7, then another aliquot shall be used for the volatile extraction procedure in Section 7.3. The aliquot of the waste subjected to the procedure in Section 7.1.1.7 might be appropriate for use for the Section 7.2 extraction if an adequate amount of solid (as determined by Section 7.1.1.9) was obtained. The amount of solid necessary is dependent upon whether a sufficient amount of extract will be produced to support the analyses. If an adequate amount of solid remains, proceed to Section 7.2.10 of the nonvolatile TCLP extraction.

7.2 Procedure When Volatiles are not Involved

A minimum sample size of 100 grams (solid and liquid phases) is recommend- ed. In some cases, a larger sample size may be appropriate, depending on the

solids content of the waste sample (percent solids, See Section 7.1.1), whether the initial liquid phase of the waste will be miscible with the aqueous extract of the solid, and whether inorganics, semivolatile organics, pesticides, and herbicides are all analytes of concern. Enough solids should be generated for extraction such that the volume of TCLP extract will be sufficient to support all of the analyses required. If the amount of extract generated by a single TCLP extraction will not be sufficient to perform all of the analyses, more than one extraction may be performed and the extracts from each combined and aliquoted for analysis.

7.2.1 If the waste will obviously yield no liquid when subjected to pressure filtration (i.e., is 100% solid, see Section 7.1.1), weigh out a subsample of the waste (100 gram minimum) and proceed to Section 7.2.9.

7.2.2 If the sample is liquid or multiphasic, liquid/solid separation is required. This involves the filtration device described in Section 4.3.2 and is outlined in Sections 7.2.3 to 7.2.8.

7.2.3 Pre-weigh the container that will receive the filtrate.

7.2.4 Assemble the filter holder and filter following the manufacturer's instructions. Place the filter on the support screen and secure. Acid wash the filter if evaluating the mobility of metals (see Section 4.4).

NOTE: Acid washed filters may be used for all nonvolatile extractions even when metals are not of concern.

7.2.5 Weigh out a subsample of the waste (100 gram minimum) and record the weight. If the waste contains <0.5% dry solids (Section 7.1.2), the liquid portion of the waste, after filtration, is defined as the TCLP extract. Therefore, enough of the sample should be filtered so that the amount of filtered liquid will support all of the analyses required of the TCLP extract. For wastes containing >0.5% dry solids (Sections 7.1.1 or 7.1.2), use the percent solids information obtained in Section 7.1.1 to determine the optimum sample size (100 gram minimum) for filtration. Enough solids should be generated by filtration to support the analyses to be performed on the TCLP extract.

7.2.6 Allow slurries to stand to permit the solid phase to settle. Wastes that settle slowly may be centrifuged prior to filtration. Use centrifugation only as an aid to filtration. If the waste is centrifuged, the liquid should be decanted and filtered followed by filtration of the solid portion of the waste through the same filtration system.

7.2.7 Quantitatively transfer the waste sample (liquid and solid phases) to the filter holder (see Section 4.3.2). Spread the waste sample evenly over the surface of the filter. If filtration of the waste at 4 °C reduces the amount of expressed liquid over what would be expressed at

room temperature, then allow the sample to warm up to room temperature in the device before filtering.

NOTE: If waste material (>1% of the original sample weight) has obviously adhered to the container used to transfer the sample to the filtration apparatus, determine the weight of this residue and subtract it from the sample weight determined in Section 7.2.5, to determine the weight of the waste sample that will be filtered.

Gradually apply vacuum or gentle pressure of 1-10 psi, until air or pressurizing gas moves through the filter. If this point is not reached under 10 psi, and if no additional liquid has passed through the filter in any 2 minute interval, slowly increase the pressure in 10 psi increments to a maximum of 50 psi. After each incremental increase of 10 psi, if the pressurizing gas has not moved through the filter, and if no additional liquid has passed through the filter in any 2 minute interval, proceed to the next 10 psi increment. When the pressurizing gas begins to move through the filter, or when the liquid flow has ceased at 50 psi (i.e., filtration does not result in any additional filtrate within a 2 minute period), stop the filtration.

NOTE: Instantaneous application of high pressure can degrade the glass fiber filter and may cause premature plugging.

7.2.8 The material in the filter holder is defined as the solid phase of the waste, and the filtrate is defined as the liquid phase. Weigh the filtrate. The liquid phase may now be either analyzed (See Section 7.2.12) or stored at 4 °C until time of analysis.

NOTE: Some wastes, such as oily wastes and some paint wastes, will obviously contain some material that appears to be a liquid. Even after applying vacuum or pressure filtration, as outlined in Section 7.2.7, this material may not filter. If this is the case, the material within the filtration device is defined as a solid and is carried through the extraction as a solid. Do not replace the original filter with a fresh filter under any circumstances. Use only one filter.

7.2.9 If the waste contains <0.5% dry solids (see Section 7.1.2), proceed to Section 7.2.13. If the waste contains >0.5% dry solids (see Section 7.1.1 or 7.1.2), and if particle size reduction of the solid was needed in Section 7.1.3, proceed to Section 7.2.10. If the waste as received passes a 9.5 mm sieve, quantitatively transfer the solid material into the extractor bottle along with the filter used to separate the initial liquid from the solid phase, and proceed to Section 7.2.11.

7.2.10 Prepare the solid portion of the waste for extraction by crushing, cutting, or grinding the waste to a surface area or particle size as described in Section 7.1.3. When the surface area or particle size has been appropriately altered, quantitatively transfer the solid

material into an extractor bottle. Include the filter used to separate the initial liquid from the solid phase.

NOTE: Sieving of the waste is not normally required. Surface area requirements are meant for filamentous (e.g., paper, cloth) and similar waste materials. Actual measurement of surface area is not recommended. If sieving is necessary, a Teflon coated sieve should be used to avoid contamination of the sample.

7.2.11 Determine the amount of extraction fluid to add to the extractor vessel as follows:

$$\text{Weight of extraction fluid} = \frac{20 \times \text{percent solids (Section 7.1.1)} \times \text{weight of waste filtered (Section 7.2.5 or 7.2.7)}}{100}$$

Slowly add this amount of appropriate extraction fluid (see Section 7.1.4) to the extractor vessel. Close the extractor bottle tightly (it is recommended that Teflon tape be used to ensure a tight seal), secure in rotary agitation device, and rotate at 30 ± 2 rpm for 18 ± 2 hours. Ambient temperature (i.e., temperature of room in which extraction takes place) shall be maintained at 23 ± 2 °C during the extraction period.

NOTE: As agitation continues, pressure may build up within the extractor bottle for some types of wastes (e.g., limed or calcium carbonate containing waste may evolve gases such as carbon dioxide). To relieve excess pressure, the extractor bottle may be periodically opened (e.g., after 15 minutes, 30 minutes, and 1 hour) and vented into a hood.

7.2.12 Following the 18 ± 2 hour extraction, separate the material in the extractor vessel into its component liquid and solid phases by filtering through a new glass fiber filter, as outlined in Section 7.2.7. For final filtration of the TCLP extract, the glass fiber filter may be changed, if necessary, to facilitate filtration. Filter(s) shall be acid-washed (see Section 4.4) if evaluating the mobility of metals.

7.2.13 Prepare the TCLP extract as follows:

7.2.13.1 If the waste contained no initial liquid phase, the filtered liquid material obtained from Section 7.2.12 is defined as the TCLP extract. Proceed to Section 7.2.14.

7.2.13.2 If compatible (e.g., multiple phases will not result on combination), combine the filtered liquid resulting from Section 7.2.12 with the initial liquid phase of the waste obtained in Section 7.2.7. This combined liquid is defined as the TCLP extract. Proceed to Section 7.2.14.

7.2.13.3 If the initial liquid phase of the waste, as obtained from Section 7.2.7, is not or may not be compatible with the filtered liquid resulting from Section 7.2.12, do not combine these liquids. Analyze these liquids, collectively defined as the TCLP extract, and combine the results mathematically, as described in Section 7.2.14.

7.2.14 Following collection of the TCLP extract, the pH of the extract should be recorded. Immediately aliquot and preserve the extract for analysis. Metals aliquots must be acidified with nitric acid to pH <2. If precipitation is observed upon addition of nitric acid to a small aliquot of the extract, then the remaining portion of the extract for metals analyses shall not be acidified and the extract shall be analyzed as soon as possible. All other aliquots must be stored under refrigeration (4 °C) until analyzed. The TCLP extract shall be prepared and analyzed according to appropriate analytical methods. TCLP extracts to be analyzed for metals shall be acid digested except in those instances where digestion causes loss of metallic analytes. If an analysis of the undigested extract shows that the concentration of any regulated metallic analyte exceeds the regulatory level, then the waste is hazardous and digestion of the extract is not necessary. However, data on undigested extracts alone cannot be used to demonstrate that the waste is not hazardous. If the individual phases are to be analyzed separately, determine the volume of the individual phases (to $\pm$ 0.5%), conduct the appropriate analyses, and combine the results mathematically by using a simple volume-weighted average:

$$\text{Final Analyte Concentration} = \frac{(V_1)(C_1) + (V_2)(C_2)}{V_1 + V_2}$$

where:

V_1 = The volume of the first phase (L).
C_1 = The concentration of the analyte of concern in the first phase (mg/L).
V_2 = The volume of the second phase (L).
C_2 = The concentration of the analyte of concern in the second phase (mg/L).

7.2.15 Compare the analyte concentrations in the TCLP extract with the levels identified in the appropriate regulations. Refer to Section 8.0 for quality assurance requirements.

7.3 Procedure When Volatiles are Involved

Use the ZHE device to obtain TCLP extract for analysis of volatile compounds only. Extract resulting from the use of the ZHE shall not be used to evaluate the mobility of nonvolatile analytes (e.g., metals, pesticides, etc.).

The ZHE device has approximately a 500 mL internal capacity. The ZHE can thus accommodate a maximum of 25 grams of solid (defined as that fraction of a

sample from which no additional liquid may be forced out by an applied pressure of 50 psi), due to the need to add an amount of extraction fluid equal to 20 times the weight of the solid phase.

Charge the ZHE with sample only once and do not open the device until the final extract (of the solid) has been collected. Repeated filling of the ZHE to obtain 25 grams of solid is not permitted.

Do not allow the waste, the initial liquid phase, or the extract to be exposed to the atmosphere for any more time than is absolutely necessary. Any manipulation of these materials should be done when cold (4 °C) to minimize loss of volatiles.

7.3.1 Pre-weigh the (evacuated) filtrate collection container (See Section 4.6) and set aside. If using a TEDLAR® bag, express all liquid from the ZHE device into the bag, whether for the initial or final liquid/solid separation, and take an aliquot from the liquid in the bag for analysis. The containers listed in Section 4.6 are recommended for use under the conditions stated in Sections 4.6.1 - 4.6.3.

7.3.2 Place the ZHE piston within the body of the ZHE (it may be helpful first to moisten the piston O-rings slightly with extraction fluid). Adjust the piston within the ZHE body to a height that will minimize the distance the piston will have to move once the ZHE is charged with sample (based upon sample size requirements determined from Section 7.3, Section 7.1.1 and/or 7.1.2). Secure the gas inlet/outlet flange (bottom flange) onto the ZHE body in accordance with the manufacturer's instructions. Secure the glass fiber filter between the support screens and set aside. Set liquid inlet/outlet flange (top flange) aside.

7.3.3 If the waste is 100% solid (see Section 7.1.1), weigh out a subsample (25 gram maximum) of the waste, record weight, and proceed to Section 7.3.5.

7.3.4 If the waste contains < 0.5% dry solids (Section 7.1.2), the liquid portion of waste, after filtration, is defined as the TCLP extract. Filter enough of the sample so that the amount of filtered liquid will support all of the volatile analyses required. For wastes containing $\geq$ 0.5% dry solids (Sections 7.1.1 and/or 7.1.2), use the percent solids information obtained in Section 7.1.1 to determine the optimum sample size to charge into the ZHE. The recommended sample size is as follows:

7.3.4.1 For wastes containing < 5% solids (see Section 7.1.1), weigh out a 500 gram subsample of waste and record the weight.

7.3.4.2 For wastes containing $\geq$ 5% solids (see Section 7.1.1), determine the amount of waste to charge into the ZHE as follows:

$$\text{Weight of waste to charge ZHE} = \frac{25}{\text{percent solids (Section 7.1.1)}} \times 100$$

Weigh out a subsample of the waste of the appropriate size and record the weight.

7.3.5 If particle size reduction of the solid portion of the waste was required in Section 7.1.3, proceed to Section 7.3.6. If particle size reduction was not required in Section 7.1.3, proceed to Section 7.3.7.

7.3.6 Prepare the waste for extraction by crushing, cutting, or grinding the solid portion of the waste to a surface area or particle size as described in Section 7.1.3. Wastes and appropriate reduction equipment should be refrigerated, if possible, to 4 °C prior to particle size reduction. The means used to effect particle size reduction must not generate heat in and of itself. If reduction of the solid phase of the waste is necessary, exposure of the waste to the atmosphere should be avoided to the extent possible.

NOTE: Sieving of the waste is not recommended due to the possibility that volatiles may be lost. The use of an appropriately graduated ruler is recommended as an acceptable alternative. Surface area requirements are meant for filamentous (e.g., paper, cloth) and similar waste materials. Actual measurement of surface area is not recommended.

When the surface area or particle size has been appropriately altered, proceed to Section 7.3.7.

7.3.7 Waste slurries need not be allowed to stand to permit the solid phase to settle. Do not centrifuge wastes prior to filtration.

7.3.8 Quantitatively transfer the entire sample (liquid and solid phases) quickly to the ZHE. Secure the filter and support screens onto the top flange of the device and secure the top flange to the ZHE body in accordance with the manufacturer's instructions. Tighten all ZHE fittings and place the device in the vertical position (gas inlet/outlet flange on the bottom). Do not attach the extract collection device to the top plate.

NOTE: If waste material (>1% of original sample weight) has obviously adhered to the container used to transfer the sample to the ZHE, determine the weight of this residue and subtract it from the sample weight determined in Section 7.3.4 to determine the weight of the waste sample that will be filtered.

Attach a gas line to the gas inlet/outlet valve (bottom flange) and, with the liquid inlet/outlet valve (top flange) open, begin applying gentle pressure of 1-10 psi (or more if necessary) to force all headspace

slowly out of the ZHE device into a hood. At the first appearance of liquid from the liquid inlet/outlet valve, quickly close the valve and discontinue pressure. If filtration of the waste at 4 °C reduces the amount of expressed liquid over what would be expressed at room tempera- ture, then allow the sample to warm up to room temperature in the device before filtering. If the waste is 100% solid (see Section 7.1.1), slowly increase the pressure to a maximum of 50 psi to force most of the headspace out of the device and proceed to Section 7.3.12.

7.3.9 Attach the evacuated pre-weighed filtrate collection container to the liquid inlet/outlet valve and open the valve. Begin applying gentle pressure of 1-10 psi to force the liquid phase of the sample into the filtrate collection container. If no additional liquid has passed through the filter in any 2 minute interval, slowly increase the pressure in 10 psi increments to a maximum of 50 psi. After each incremental increase of 10 psi, if no additional liquid has passed through the filter in any 2 minute interval, proceed to the next 10 psi increment. When liquid flow has ceased such that continued pressure filtration at 50 psi does not result in any additional filtrate within a 2 minute period, stop the filtration. Close the liquid inlet/outlet valve, discontinue pressure to the piston, and disconnect and weigh the filtrate collection container.

NOTE: Instantaneous application of high pressure can degrade the glass fiber filter and may cause premature plugging.

7.3.10 The material in the ZHE is defined as the solid phase of the waste and the filtrate is defined as the liquid phase.

NOTE: Some wastes, such as oily wastes and some paint wastes, will obviously contain some material that appears to be a liquid. Even after applying pressure filtration, this material will not filter. If this is the case, the material within the filtration device is defined as a solid and is carried through the TCLP extraction as a solid.

If the original waste contained <0.5% dry solids (see Section 7.1.2), this filtrate is defined as the TCLP extract and is analyzed directly. Proceed to Section 7.3.15.

7.3.11 The liquid phase may now be either analyzed immediately (See Sections 7.3.13 through 7.3.15) or stored at 4 °C under minimal headspace conditions until time of analysis. Determine the weight of extraction fluid #1 to add to the ZHE as follows:

$$\text{Weight of extraction fluid} = \frac{20 \times \text{percent solids (Section 7.1.1)} \times \text{weight of waste filtered (Section 7.3.4 or 7.3.8)}}{100}$$

7.3.12 The following Sections detail how to add the appropriate amount of extraction fluid to the solid material within the ZHE and agitation of the ZHE vessel. Extraction fluid #1 is used in all cases (See Section 5.7).

7.3.12.1 With the ZHE in the vertical position, attach a line from the extraction fluid reservoir to the liquid in- let/outlet valve. The line used shall contain fresh extraction fluid and should be preflushed with fluid to eliminate any air pockets in the line. Release gas pressure on the ZHE piston (from the gas inlet/outlet valve), open the liquid inlet/outlet valve, and begin transferring extraction fluid (by pumping or similar means) into the ZHE. Continue pumping extraction fluid into the ZHE until the appropriate amount of fluid has been introduced into the device.

7.3.12.2 After the extraction fluid has been added, immediately close the liquid inlet/outlet valve and disconnect the extraction fluid line. Check the ZHE to ensure that all valves are in their closed positions. Manually rotate the device in an end-over-end fashion 2 or 3 times. Reposition the ZHE in the vertical position with the liquid inlet/outlet valve on top. Pressurize the ZHE to 5-10 psi (if necessary) and slowly open the liquid inlet/outlet valve to bleed out any headspace (into a hood) that may have been introduced due to the addition of extraction fluid. This bleeding shall be done quickly and shall be stopped at the first appearance of liquid from the valve. Re-pressurize the ZHE with 5-10 psi and check all ZHE fittings to ensure that they are closed.

7.3.12.3 Place the ZHE in the rotary agitation appara- tus (if it is not already there) and rotate at 30 $\pm$ 2 rpm for 18 $\pm$ 2 hours. Ambient temperature (i.e., temperature of room in which extraction occurs) shall be maintained at 23 $\pm$ 2 °C during agita- tion.

7.3.13 Following the 18 $\pm$ 2 hour agitation period, check the pressure behind the ZHE piston by quickly opening and closing the gas inlet/outlet valve and noting the escape of gas. If the pressure has not been maintained (i.e., no gas release observed), the device is leaking. Check the ZHE for leaking as specified in Section 4.2.1, and perform the extraction again with a new sample of waste. If the pressure within the device has been maintained, the material in the extractor vessel is once again separated into its component liquid and solid phases. If the waste contained an initial liquid phase, the liquid may be filtered directly into the same filtrate collection container (i.e., TEDLAR® bag) holding the initial liquid phase of the waste. A separate filtrate collection container must be used if combining would create multiple phases, or there is not enough volume left within the filtrate collection container. Filter through the glass fiber filter, using the ZHE device as discussed in Section 7.3.9. All extract shall be filtered and collected if the

TEDLAR® bag is used, if the extract is multiphasic, or if the waste contained an initial liquid phase (see Sections 4.6 and 7.3.1).

NOTE: An in-line glass fiber filter may be used to filter the material within the ZHE if it is suspected that the glass fiber filter has been ruptured.

7.3.14 If the original waste contained no initial liquid phase, the filtered liquid material obtained from Section 7.3.13 is defined as the TCLP extract. If the waste contained an initial liquid phase, the filtered liquid material obtained from Section 7.3.13 and the initial liquid phase (Section 7.3.9) are collectively defined as the TCLP extract.

7.3.15 Following collection of the TCLP extract, immediately prepare the extract for analysis and store with minimal headspace at 4 °C until analyzed. Analyze the TCLP extract according to the appropriate analytical methods. If the individual phases are to be analyzed separately (i.e., are not miscible), determine the volume of the individual phases (to 0.5%), conduct the appropriate analyses, and combine the results mathematically by using a simple volume-weighted average:

$$\text{Final Analyte Concentration} = \frac{(V_1)(C_1) + (V_2)(C_2)}{V_1 + V_2}$$

where:

V_1 = The volume of the first phases (L).
C_1 = The concentration of the analyte of concern in the first phase (mg/L).
V_2 = The volume of the second phase (L).
C_2 = The concentration of the analyte of concern in the second phase (mg/L).

7.3.16 Compare the analyte concentrations in the TCLP extract with the levels identified in the appropriate regulations. Refer to Section 8.0 for quality assurance requirements.

8.1 QUALITY ASSURANCE

8.2 A minimum of one blank (using the same extraction fluid as used for the samples) must be analyzed for every 20 extractions that have been conducted in an extraction vessel.

8.3 A matrix spike shall be performed for each waste type (e.g., wastewater treatment sludge, contaminated soil, etc.) unless the result exceeds the regulatory level and the data are being used solely to demonstrate that the waste property exceeds the regulatory level. A minimum of one matrix spike must be analyzed for each analytical batch. As a minimum, follow the matrix spike addition guidance provided in each analytical method.

8.3.1 Matrix spikes are to be added after filtration of the TCLP extract and before preservation. Matrix spikes should not be added prior to TCLP extraction of the sample.

8.3.2 In most cases, matrix spikes should be added at a concentration equivalent to the corresponding regulatory level. If the analyte concentration is less than one half the regulatory level, the spike concentration may be as low as one half of the analyte concentra- tion, but may not be not less than five times the method detection limit. In order to avoid differences in matrix effects, the matrix spikes must be added to the same nominal volume of TCLP extract as that which was analyzed for the unspiked sample.

8.3.3 The purpose of the matrix spike is to monitor the performance of the analytical methods used, and to determine whether matrix interferences exist. Use of other internal calibration methods, modification of the analytical methods, or use of alternate analytical methods may be needed to accurately measure the analyte concentration in the TCLP extract when the recovery of the matrix spike is below the expected analytical method performance.

8.3.4 Matrix spike recoveries are calculated by the following formula:

$\%R\ (\%Recovery) = 100\ (X_s - X_u)/K$

where:
X_s = measured value for the spiked sample,
X_u = measured value for the unspiked sample, and
K = known value of the spike in the sample.

8.4 All quality control measures described in the appropriate analytical methods shall be followed.

8.5 The use of internal calibration quantitation methods shall be employed for a metallic contaminant if: (1) Recovery of the contaminant from the TCLP extract is not at least 50% and the concentration does not exceed the regulatory level, and (2) The concentration of the contaminant measured in the extract is within 20% of the appropriate regulatory level.

8.4.1. The method of standard additions shall be employed as the internal calibration quantitation method for each metallic contaminant.

8.4.2 The method of standard additions requires preparing calibration standards in the sample matrix rather than reagent water or blank solution. It requires taking four identical aliquots of the solution and adding known amounts of standard to three of these aliquots. The forth aliquot is the unknown. Preferably, the first addition should be prepared so that the resulting concentration is approximately 50% of the expected concentration of the sample. The second and third additions should be prepared so that the concentrations are approximately 100% and

150% of the expected concentration of the sample. All four aliquots are maintained at the same final volume by adding reagent water or a blank solution, and may need dilution adjustment to maintain the signals in the linear range of the instrument technique. All four aliquots are analyzed.

8.4.3 Prepare a plot, or subject data to linear regression, of instrument signals or external-calibration-derived concentrations as the dependant variable (y-axis) versus concentrations of the additions of standard as the independent variable (x-axis). Solve for the intercept of the abscissa (the independent variable, x-axis) which is the concentration in the unknown.

8.4.4 Alternately, subtract the instrumental signal or external- calibration-derived concentration of the unknown (unspiked) sample from the instrumental signals or external-calibration-derived concentrations of the standard additions. Plot or subject to linear regression of the corrected instrument signals or external-calibration-derived concentra- tions as the dependant variable versus the independent variable. Derive concentrations for unknowns using the internal calibration curve as if it were an external calibration curve.

8.5 Samples must undergo TCLP extraction within the following time periods:

SAMPLE MAXIMUM HOLDING TIMES [DAYS]

	From: Field collection To: TCLP extraction	From: TCLP extraction To: Preparative extraction	From: Preparative extraction To: Determinative analysis	Total elapsed time
Volatiles	14	NA	14	28
Semi-volatiles	14	7	40	61
Mercury	28	NA	28	56
Metals, except mercury	180	NA	180	360

NA = Not applicable

If sample holding times are exceeded, the values obtained will be considered minimal concentrations. Exceeding the holding time is not acceptable in establishing that a waste does not exceed the regulatory level. Exceeding the holding time will not invalidate characterization if the waste exceeds the regulatory level.

9.1 METHOD PERFORMANCE

9.2 Ruggedness. Two ruggedness studies have been performed to determine the effect of various perturbations on specific elements of the TCLP protocol. Ruggedness testing determines the sensitivity of small procedural variations which might be expected to occur during routine laboratory application.

9.2.1 Metals - The following conditions were used when leaching a waste for metals analysis:

Varying Conditions	
Liquid/Solid ratio	19:1 vs. 21:1
Extraction time	16 hours vs. 18 hours
Headspace	20% vs. 60%
Buffer #2 acidity	190 meq vs. 210 meq
Acid-washed filters	yes vs. no
Filter type	0.7 µm glass fiber vs. 0.45 µm vs. polycarbonate
Bottle type	borosilicate vs. flint glass

Of the seven method variations examined, acidity of the extraction fluid had the greatest impact on the results. Four of 13 metals from an API separator sludge/electroplating waste (API/EW) mixture and two of three metals from an ammonia lime still bottom waste were extracted at higher levels by the more acidic buffer. Because of the sensitivity to pH changes, the method requires that the extraction fluids be prepared so that the final pH is within $\pm$ 0.05 units as specified.

9.2.2 Volatile Organic Compounds - The following conditions were used when leaching a waste for VOC analysis:

Varying Conditions	
Liquid/Solid ratio	19:1 vs. 21:1
Headspace	0% vs. 5%
Buffer #1 acidity	60 meq vs. 80 meq
Method of storing extract	Syringe vs. Tedlar® bag
Aliquotting	yes vs. no
Pressure behind piston	0 psi vs. 20 psi

None of the parameters had a significant effect on the results of the ruggedness test.

9.3 Precision. Many TCLP precision (reproducibility) studies have been performed, and have shown that, in general, the precision of the TCLP is comparable to or exceeds that of the EP toxicity test and that method precision is adequate. One of the more significant contributions to poor precision appears to be related to sample homogeneity and inter-laboratory variation (due to the nature of waste materials).

9.3.1 Metals - The results of a multi-laboratory study are shown in Table 6, and indicate that a single analysis of a waste may not be adequate for waste characterization and identification requirements.

9.3.2 Semi-Volatile Organic Compounds - The results of two studies are shown in Tables 7 and 8. Single laboratory precision was excellent with greater than 90 percent of the results exhibiting an RSD less than 25 percent. Over 85 percent of all individual compounds in the multi-laboratory study fell in the RSD range of 20 - 120 percent. Both studies concluded that the TCLP provides adequate precision. It was also determined that the high acetate content of the extraction fluid did not present problems (i.e., column degradation of the gas chromatograph) for the analytical conditions used.

9.3.3 Volatile Organic Compounds - Eleven laboratories participated in a collaborative study of the use of the ZHE with two waste types which were fortified with a mixture of VOCs. The results of the collaborative study are shown in Table 9. Precision results for VOCs tend to occur over a considerable range. However, the range and mean RSD compared very closely to the same collaborative study metals results in Table 6. Blackburn and Show concluded that at the 95% level of signifi- cance: 1) recoveries among laboratories were statistically similar, 2) recoveries did not vary significantly between the two sample types, and 3) each laboratory showed the same pattern of recovery for each of the two samples.

Modification Types Based on Regulatory Descriptions

1. General Classifications of Permit Modifications and Crosswalk to Applicable Regulations.

2. Classification of Permit Modifications as listed in Appendix I to §270.42

1. General Classifications of Permit Modifications and Crosswalk to Applicable Regulations.

Modifications Category in Appendix I to §270.42	40 CFR Reference
B. General Facility Standards	40 CFR 264 Subpart B
C. Ground-Water Protection	40 CFR 264 Subpart F
D. Closure	40 CFR 264 Subpart G 264.111 – 264.115
E. Post-Closure	40 CFR 264 Subpart G 264.116 – 264.120
F. Containers	40 CFR 264 Subpart I
G. Tanks	40 CFR 264 Subpart J
H. Surface Impoundments	40 CFR 264 Subpart K
I. Enclosed Waste Piles	40 CFR 264 Subpart L
J. Landfills and Unenclosed Waste Piles	40 CFR 264 Subpart N
K. Land Treatment	40 CFR 264 Subpart M
L. Incinerators, Boilers, and Industrial Furnaces	40 CFR 264 Subpart O
M. Containment Buildings	40 CFR 264 Subpart DD
N. Corrective Action	40 CFR 264 Subpart S
O. Burden Reduction	various

40 CFR 270 Subparts

SUBPART O - INCINERATORS - in addition to L above, refer to 40 CFR 270.42(j) and 270.42(k)
SUBPART EE - HAZARDOUS WASTE MUNITIONS AND EXPLOSIVES STORAGE -refer to 40 CFR 270.42(h)

40 CFR 264 Subparts without a specific Permit Modification Category in 40 CFR 270.42 Appendix I

SUBPART C - PREPAREDNESS AND PREVENTION
SUBPART D - CONTINGENCY PLAN AND EMERGENCY PROCEDURES
SUBPART E - MANIFEST SYSTEM, RECORDKEEPING, AND REPORTING
SUBPART H - FINANCIAL REQUIREMENTS
SUBPART W - DRIP PADS
SUBPART X - MISCELLANEOUS UNITS
SUBPART AA - AIR EMISSION STANDARDS FOR PROCESS VENTS
SUBPART BB - AIR EMISSION STANDARDS FOR EQUIPMENT LEAKS
SUBPART CC - AIR EMISSION STANDARDS FOR TANKS, SURFACE IMPOUNDMENTS, AND CONTAINERS
SUBPART EE - HAZARDOUS WASTE MUNITIONS AND EXPLOSIVES STORAGE

2. Classification of Permit Modifications as listed in in Appendix I to §270.42

Modifications	Class	Minor (Mi)
A. ***General Permit Provisions***		
1. Administrative and informational changes	1	Mi*
2. Correction of typographical errors	1	Mi*
