Non-discrimination statement

DEQ does not discriminate on the basis of race, color, national origin, disability, age, sex, religion, sexual orientation, gender identity, or marital status in the administration of its programs and activities. Visit DEQ's [Civil Rights and Environmental Justice page](#).

Acknowledgments

The Willamette Subbasins Temperature TMDL and Water Quality Management Plan would not be possible without the support, contributions, and review of the following:

Julia Bond	City of Portland
Dan Brown	Oregon Department of Environmental Quality
Rob Burkhart	Oregon Department of Environmental Quality
Gene Foster	Oregon Department of Environmental Quality
Alex Liverman	Oregon Department of Environmental Quality
Michele Martin	Oregon Department of Environmental Quality
James McConaghie	Oregon Department of Environmental Quality
Jordan Palmeri	Oregon Department of Environmental Quality
Josh Seeds	Oregon Department of Environmental Quality
Debra Sturdevant	Oregon Department of Environmental Quality
Jennifer Wigal	Oregon Department of Environmental Quality
Sen Bai	Tetra Tech
Mustafa Faizullahoy	Tetra Tech
Aileen Molloy	Tetra Tech
Joel Achenbach	U.S. Environmental Protection Agency, Region 10 (formerly of)
Ben Cope	U.S. Environmental Protection Agency, Region 10
Gunnar Johnson	U.S. Environmental Protection Agency, Region 10
Lisa Kusnierz	U.S. Environmental Protection Agency, Region 10
Peter Leinenbach	U.S. Environmental Protection Agency, Region 10
Rebecca Veiga-Nascimento	U.S. Environmental Protection Agency, Region 10
Jenny Wu	U.S. Environmental Protection Agency, Region 10
Laurel Stratton Garvin	U.S. Geological Survey

In addition, we would like to thank the TMDL Rule Advisory Committee Members, Tribal Nations, and all the individuals or organizations who provided data or took time to review and provide comments to DEQ.

Wastewater Treatment Plant

1 Introduction

This Total Maximum Daily Load (TMDL) project includes the following Willamette Subbasins: Coast Fork Willamette, McKenzie, Middle Fork Willamette, Upper Willamette, Middle Willamette, Molalla-Pudding, North Santiam, South Santiam, Lower Willamette, and Clackamas Subbasins. This TMDL was adopted by reference in Oregon Administrative Rules OAR 340-42-0090.

OAR 340-42-0040(3) requires the Oregon Department of Environmental Quality (DEQ) or the Oregon Environmental Quality Commission (EQC) to prioritize and schedule TMDLs for completion considering various factors outlined in the rule. Temperature TMDLs for the Willamette Subbasins were identified as a high priority on Oregon's TMDL priority ranking submitted with Oregon's 2022 Integrated Report and due to court order to Oregon and the Environmental Protection Agency (EPA) to establish TMDLs to replace the temperature TMDLs developed as part of the 2006 Willamette Basin TMDL (action ID 30674) and the 2008 Molalla-Pudding Subbasin TMDL and Water Quality Management Plan (WQMP) (action ID 35888) (**Table 1-1**).

1.1 Previous TMDLs

In 2006 and 2008 DEQ issued, and EPA approved, two TMDL actions addressing temperature impairments (**Table 1-1**) within the project area for the Willamette Subbasins temperature TMDLs. Once approved by EPA, the Willamette Subbasins TMDLs for temperature will replace the temperature TMDLs listed in **Table 1-1**. TMDLs for other water quality impaired parameters listed in **Table 1-1** are still effective.

Table 1-1: Summary of previous temperature TMDLs developed for the Willamette Subbasins.

TMDL Action ID	TMDL Name	EPA Approval Date	Water Quality Impairments Addressed
30674	Willamette Basin TMDL	9/29/2006	Ammonia, Bacteria (water contact recreation), DDT 4,4', Dieldrin, Dissolved Oxygen, Mercury, Temperature, Turbidity
35888	Molalla-Pudding Subbasin TMDL and WQMP	12/31/2008	Bacteria (water contact recreation), Chlordane, DDD 4,4', DDE 4,4', DDT 4,4', Dieldrin, Iron, Nitrates, Temperature

1.2 TMDL administrative process and public participation

Following completion of DEQ's drafting process, including engagement of a rule advisory committee on the fiscal impact statement and aspects of the rule, this revised temperature TMDL for the Willamette Subbasins was adopted by EQC, by reference, into rule section OAR 340-042-0090. Any subsequently amended or renumbered rules cited in this document are intended to apply.

DEQ convened a rule advisory committee to provide input on drafts of the TMDL, WQMP, Technical Support Document (TSD) (DEQ, 2023a and 2023b), fiscal and economic impacts, and Environmental Justice and Racial Equity. The committee met on February 23, 2023, and April 6, 2023. The agency held two informational webinars about this TMDL. A public comment period was held from January 10 through March 15, 2024. DEQ held a public hearing on February 16, 2024. DEQ considered all input received during these public participation opportunities and used input to guide the analyses and preparation of documents. DEQ developed a response to comments that is available online. EQC adopted the Willamette Subbasins TMDL and WQMP rule on August 6, 2024. EPA approved the TMDL on September 12, 2024.

The TMDL and WQMP were revised to add temperature TMDLs for the Willamette River, Multnomah Channel, and tributaries to the Willamette River downstream of the following dams: River Mill Dam, Detroit Dam, Foster Dam, Fern Ridge Dam, Dexter Dam, Fall Creek Dam, Dorena Dam, and Cottage Grove Dam. The name of this project area is the Willamette River mainstem and major tributaries. DEQ convened a rule advisory committee for these TMDL additions. The rule advisory committee provided input on drafts of the updated TMDL, WQMP, Technical Support Document, fiscal and economic impacts, and Environmental Justice and Racial Equity. The committee met on March 14, 2024, May 16, 2024, and July 30, 2024. A public comment period was held from August 9, 2024 through October 14, 2024. DEQ extended the public comment period for 21 days at the request of the public. DEQ held a public hearing on September 17, 2024. DEQ considered all input received during these public participation opportunities and used input to guide the analyses and preparation of documents. DEQ developed a response to comments that is available online. EQC adopted the amended Willamette Subbasins TMDL and WQMP rule on May 8, 2025.

2 TMDL name and location

Per OAR 340-042-0040(4)(a), this element describes the geographic area for which the TMDL was developed.

The Willamette Subbasins comprise ten 8-digit hydrologic unit code (HUC) subbasins, including the Middle Fork Willamette Subbasin (HUC 17090001), Coast Fork Willamette Subbasin (HUC 17090002), Upper Willamette Subbasin (HUC 17090003), McKenzie Subbasin (HUC 17090004), North Santiam Subbasin (HUC 17090005), the South Santiam Subbasin (HUC 17090006), Middle Willamette Subbasin (HUC 17090007), Molalla-Pudding Subbasin (HUC 17090009), Clackamas Subbasin (HUC 17090011), and Lower Willamette Subbasin (HUC 17090012) (**Table 2-1**).

Temperature TMDLs for the Willamette Subbasins address all Category 5 listed assessment units (AUs) impaired for temperature on Oregon's 2022 Section 303(d) list (**Table 2-2** through **Table 2-11**) and, as applicable, any AUs identified as temperature impaired in the future. In total, the TMDL applies to 958 unique AUs, of which 258 are impaired for temperature. Some of these assessment units have both year-round and spawning use designations impaired. If both use designations are impaired, it is counted as two Category 5 303(d) listings. Therefore, the TMDL addresses a total of 329 Category 5 temperature listings identified on the 2022 Integrated Report.

The loading capacity, allocations, surrogate measures, and implementation framework apply to all waters in the Willamette Subbasins determined to be waters of the state as defined under Oregon Revised Statutes ORS 468B.005(10), including all perennial and intermittent streams that have surface flow or residual pools during the TMDL allocation period.

The TMDL implementation framework is presented in the Willamette Subbasins TMDL WQMP and includes implementation activities and timeframes to improve water quality, as well as measures of success. These and other protection plan elements are further explained in Section 12.

The map in **Figure 2-1** provides an overview of where the temperature TMDLs are applicable. Appendix D of the Willamette Subbasin TSD provides a list of all AUs addressed by the TMDL.

Table 2-1: HUC8 codes and names in the Willamette Subbasins.

HUC8	Subbasin Name
17090001	Middle Fork Willamette
17090002	Coast Fork Willamette
17090003	Upper Willamette
17090004	McKenzie
17090005	North Santiam
17090006	South Santiam
17090007	Middle Willamette
17090009	Molalla-Pudding
17090011	Clackamas
17090012	Lower Willamette

Figure 2-1: Willamette Subbasins temperature TMDLs project area overview.

Table 2-2 through **Table 2-11** present stream AUs within the Willamette Subbasins that were listed as impaired for temperature on DEQ's 2022 Clean Water Act Section 303(d) List (as part of Oregon's Integrated Report), which was approved by the EPA on September 1, 2022. Status category designations are prescribed by Sections 305(b) and 303(d) of the Clean Water Act. AUs listed in Category 5 (i.e., designated use is not supported or a water quality standard is not attained) require development of a TMDL. Locations of these listed segments are depicted in **Figure 2-2**.

Figure 2-2: Willamette Subbasins Category 5 temperature impairments on the 2022 Integrated Report.

3 Pollutant identification

As stated in OAR 340-042-0040(4)(b), this element identifies the pollutants causing impairment of water quality that are addressed by these TMDLs. The associated water quality standards and beneficial uses are identified in Section 4.

Temperature is the water quality parameter of concern, but heat or thermal loading is the pollutant of concern causing impairment. Heat caused by human activities are of particular concern.

EPA regulations (40 CFR 130.2(i)) and OAR 340-042-0040(O)(5)(b) allow for TMDLs to utilize other appropriate measures (or surrogate measures). Surrogate measures are defined in OAR 340-042-0030(14) as “substitute methods or parameters used in a TMDL to represent pollutants.” In accordance with OAR 340-042-0040(5)(b), DEQ used effective shade as a surrogate measure for thermal loading caused by excessive solar radiation. Effective shade is the percent of the daily solar radiation flux blocked by vegetation and topography. Implementation of the surrogate measures ensures achievement of necessary pollutant reductions and the nonpoint load allocations for this temperature TMDL.

4 Water quality standards and beneficial uses

As stated in OAR 340-042-0040(4)(c), this element identifies the beneficial uses in the basin, specifying the most sensitive beneficial use, and the relevant water quality standards established in OAR 340-041-0202 through 340-041-0975.

Table 4-1 and **Table 4-2** specify the designated beneficial uses in the Willamette Subbasins surface water and the applicable numeric and narrative water quality standards and antidegradation rule and policy addressed by these TMDLs, as well as indicate the most sensitive beneficial uses related to each standard. These TMDLs are designed such that meeting water quality standards for the most sensitive beneficial uses will be protective of all other uses for that parameter. Oregon’s water quality standards for temperature are designed to protect fish and aquatic life uses. Fish and aquatic life use is the most temperature sensitive beneficial use.

Table 4-1: Designated beneficial uses in the Willamette Subbasins as identified in OAR 340-041-0340 Table 340A.

Commercial Navigation & Transportation	

Table 4-2: Summary of applicable temperature water quality standards.

Rule Citation	Summary of applicable standards	Waters where standards are applicable
Statewide Narrative Criteria OAR 340-041-0007(1)	The highest and best practicable treatment and/or control of wastes, activities, and flows must in every case be provided so as to maintain dissolved oxygen and overall water quality at the highest possible levels and <u>water temperatures</u> , coliform bacteria concentrations, dissolved chemical substances, toxic materials, radioactivity, turbidities, color, odor and other deleterious factors at the lowest possible levels.	All waters of the state
Biologically Based Numeric Criteria OAR 340-041-0028(4) OAR 340-041-0340 Figures 340A and 340B	(a) The 7-day average maximum temperature of a stream identified as having salmon and steelhead spawning use may not exceed 13.0°C (55°F) at the times indicated on maps and tables (b) The 7-day average maximum temperature of a stream identified as having core cold water habitat use may not exceed 16.0°C (60.8°F) (c) The 7-day average maximum temperature of a stream identified as having salmon and trout rearing and migration use may not exceed 18.0°C (64.4°F) (d) The 7-day average maximum temperature of a stream identified as having a migration corridor use may not exceed 20.0°C (68.0°F) and cold water refugia that are sufficiently distributed. (f) The 7-day average maximum temperature may of a stream identified as having bull trout spawning and juvenile rearing use not exceed 12.0°C (53.6 °F). From August 15 through May 15 there may be no more than a 0.3°C (0.5°F) increase between the water temperature immediately upstream of Carmen reservoir on the Upper McKenzie River and the water temperature immediately downstream of the spillway when the ambient seven-day-average maximum stream temperature is 9.0°C (48°F) or greater, and no more than a 1.0°C (1.8°F) increase when the seven-day-average stream temperature is less than 9°C.	See OAR Figures 340A and 340B (Figure 4-1 and Figure 4-2 in this document)
Natural Lakes OAR 340-041-0028(6)	Natural lakes may not be warmed by more than 0.3°C (0.5°F) above the natural condition unless a greater increase would not reasonably be expected to adversely affect fish or other aquatic life.	Natural lakes or natural lakes that have been modified

Rule Citation	Summary of applicable standards	Waters where standards are applicable
Cool Water Species OAR 340-041-0028(9)	No increase in temperature is allowed that would reasonably be expected to impair cool water species. See Section 4.1 for interpretation of this narrative standard to temperature targets.	Long Tom River and Rickreall Creek. See OAR Figures 340A and 340B (Figure 4-1 and Figure 4-2 in this document)
Protecting Cold Water OAR 340-041-0028(11)	(a) Except as described in subsection (c) of this rule, waters of the State that have summer seven-day-average maximum ambient temperatures that are colder than the biologically based criteria in section (4) of this rule, may not be warmed by more than 0.3°C (0.5°F) above the colder water ambient temperature, by all sources taken together at the point of maximum impact.	Cold water
Minimum Duties OAR 340-041-0028(12)	(a) Minimum Duties. There is no duty for anthropogenic sources to reduce heating of the waters of the State below their natural condition. Similarly, each anthropogenic point and nonpoint source is responsible only for controlling the thermal effects of its own discharge or activity in accordance with its overall heat contribution. In no case may a source cause more warming than that allowed by the human use allowance.	All waters of the state
Human Use Allowance OAR 340-041-0028(12)	(b) Human Use Allowance. Insignificant additions of heat are authorized in waters that exceed the applicable temperature criteria. (B) Following a temperature TMDL or other cumulative effects analysis, wasteload and load allocations will restrict all NPDES point sources and nonpoint sources to a cumulative increase of no greater than 0.3°C (0.5°F) above the applicable criteria after complete mixing in the waterbody, and at the point of maximum impact.	
Antidegradation OAR 340-041-0004 and 40 CFR 131.12(a)(2)	(3)(c) Insignificant temperature increases authorized under OAR 340-041-0028(11) and (12) are not considered a reduction in water quality. (5)(a) Riparian Restoration Activities Exemption: When DEQ determines that activities to restore geomorphology or riparian vegetation have a net ecological benefit, antidegradation review is not needed.	

Figure 4-1: Fish use designations in the Willamette Subbasins TMDL project area.

Figure 4-2: Salmon and steelhead spawning use designations in the Willamette Subbasins TMDL project area.

4.1 Cool water species

The narrative cool water species criterion in rule at OAR 340-041-0028(9)(a) states that “No increase in temperature is allowed that would reasonably be expected to impair cool water species.” The Long Tom River (Upper Willamette Subbasin) and Rickreall Creek (Middle Willamette Subbasin) are the only waterbodies designated for cool water species use in the Willamette Subbasins.

4.1.1 Long Tom River

The cool water species designation on the Long Tom River applies from the mouth at the confluence with the Willamette River (river mile 0) to Fern Ridge Dam (approximate river mile 24.1). In consultation with ODFW, DEQ determined what cool water species are present in the Long Tom River and translated the narrative criterion into a target temperature based on the thermal tolerance information available for those species. Redside shiner (*Richardsonius balteatus*) are the most temperature sensitive cool water species in the Long Tom River with studies showing an upper lethal temperature threshold between 22.8°C and 27.7°C (Black, 1953). DEQ also determined that Chinook Salmon (*Oncorhynchus tshawytscha*) are present from approximately November 1 to June 14. Spawning of Chiselmouth, Northern Pikeminnow, Peamouth, and Mountain Sucker could occur in the lower reach between April and July. These species initiate spawning when water temperatures exceed 12°C to 18°C. DEQ will rely upon the 18.0°C target temperature established for protection of salmon and trout rearing and migration uses suggested by EPA guidance (EPA, 2003) and adopted in Oregon's water quality standards (OAR 340-041-0028 (4)(c)).

Based on these findings, the temperature targets (**Table 4-3**) for the Long Tom River are:

- 1) 24.0°C + the 0.3°C human use allowance (HUA) from June 15 through October 31 (based on thermal tolerance for Redside Shiner);
- 2) 18.0°C + HUA from November 1 to June 14 (Based on Spring Chinook rearing and juvenile migration; spawning preferences for Mountain Sucker, Peamouth, and Chiselmouth).

Table 4-3: Summary of temperature targets implementing the cool water species narrative in lower Long Tom River.

Time period	7DADM Temperature Target (°C)	Most Temperature Sensitive Species
June 15 – October 31	24.0 + 0.3 HUA	Redside shiner (<i>Richardsonius balteatus</i>)
November 1 – June 14	18.0 + 0.3 HUA	Chinook Salmon (<i>Oncorhynchus tshawytscha</i>)

If 7DADM temperatures trend to always being cooler than temperature targets presented in Table 4 3, the protecting cold water criterion at OAR 340-041-0028 (11) shall be applied with the 0.3°C human use allowance (HUA) based on an increase above the cooler ambient temperature.

Analysis and rationale for the numeric temperature targets are further described in the TMDL Technical Support Document, Section 4.8.

The mixing zone and thermal plume limitations in OAR 340-041-0053 (2)(E)(d) will provide further protections against potential migration blockages and acute impacts. This TMDL assumes assessment and application of thermal plume limitations, as necessary, will be completed during the NPDES permit renewal process.

4.1.2 Rickreall Creek

The cool water species designation on Rickreall Creek applies from the mouth at the confluence of the Willamette River (river mile 0) to the east end of Dallas City Park at approximately river mile 14. In consultation with the Oregon Department of Fish & Wildlife (ODFW), DEQ determined what cool water species are present in Rickreall Creek and translated the narrative criterion into a target temperature based on the thermal tolerance information available for those

species. Prickly sculpin are the most temperature sensitive cool water species in lower Rickreall Creek with studies showing complete survival after 24 hours at 22.8°C (Black, 1953). DEQ also determined that adult winter steelhead (*Oncorhynchus mykiss*), Coho salmon, and Chinook salmon may be migrating through the lower reach of Rickreall Creek, and juvenile winter steelhead or Coastal Cutthroat trout (*Oncorhynchus clarkii*) may be rearing in lower Rickreall Creek. Based on ODFW's timing tables, steelhead may migrate through lower Rickreall Creek from February 15 through May 31. In addition, there may be resident trout present in this segment, particularly at the upper end, from October through spring. DEQ will rely upon the 18.0°C target temperature established for protection of salmon and trout rearing and migration uses suggested by EPA's guidance (EPA, 2003) and adopted in Oregon's water quality standards (OAR 340-041-0028 (4)(c)).

Based on these findings, from June 1 to September 30, where the cool water species criterion applies in Rickreall Creek, warming from anthropogenic sources shall be limited to a cumulative increase of no greater than 0.3°C above 22.8°C after complete mixing in the waterbody, and at the POMI. During the remainder of the year (October 1 – May 31), the numeric target protecting cool water fish and migrating or rearing cold water fish is an instream 7-day average daily maximum (7DADM) temperature target of 18.0°C plus an insignificant addition of heat for human use equal to 0.3°C after complete mixing in the waterbody, and at the POMI. A summary of the temperature targets are presented in **Table 4-4**.

The provisions of the protecting cold water criterion at OAR 340-41-0028(11) are also incorporated into the temperature target. If ambient 7DADM temperatures trend to always being cooler than both temperature targets presented in **Table 4-4** and all exceptions outlined in OAR 340-41-0028(11)(c) are not applicable, the protecting cold water shall be applied with the 0.3°C HUA based on an increase above the cooler ambient temperature.

Analysis and rationale for the numeric temperature targets are further described in the TMDL Technical Support Document Section 4.8.

The mixing zone and thermal plume limitations in OAR 340-041-0053 (2)(E)(d) will provide further protections against potential migration blockages and acute impacts. This TMDL assumes assessment and application of thermal plume limitations, as necessary, will be completed during the NPDES permit renewal process.

Table 4-4: Summary of temperature targets implementing the cool water species narrative in lower Rickreall Creek.

Time period	7DADM Temperature Target (°C)	Most Temperature Sensitive Species
June 1 – September 30	22.8 + 0.3 HUA	Prickly sculpin (<i>Cottus asper</i>)
October 1 – May 31	18.0 + 0.3 HUA	Winter steelhead (<i>Oncorhynchus mykiss</i>)

4.2 Natural lakes narrative

The narrative natural lakes criterion at OAR 340-041-0028(6) states that natural lakes may not be warmed by more than 0.3°C (0.5°F) above the natural condition unless a greater increase would not reasonably be expected to adversely affect fish or other aquatic life. Absent a discharge or human modification that would reasonably be expected to increase temperature, DEQ will presume that the ambient temperature of a natural lake is the same as its natural thermal condition.

The HUA assigned to anthropogenic sources in this TMDL do not exceed 0.3°C. Therefore, any increase above the natural condition temperatures shall be implemented so the target temperature plus 0.3°C HUA is protective of fish or other aquatic life.

For the purpose of applying the natural lakes criterion, ambient temperatures has the same meaning as defined in OAR 340-041-0002(2) where ambient means the temperature measured at a specific time and place. The selected location for measuring ambient temperature must be representative of the lake in the vicinity of the point being measured. The sampling approach and number of monitoring locations may vary depending on the lake size, temperature variability, and stratification regime. Monitoring and interpretation approaches are further discussed in TSD Section 4.7. Consistent with other temperature criteria, the 7DADM temperatures will be used for characterizing ambient or natural condition temperatures.

4.3 Numeric water quality targets

TMDLs must contain numeric water quality targets. The targets represent the instream endpoint that ensures all applicable temperature water quality standards are attained and beneficial uses are protected. Temperature targets summarized in Table 4-5 are similar to the water quality standards summarized in Table 4-2 but include application of water quality standard implementation provisions, relevant narrative provisions, and the antidegradation policy.

Table 4-5: Summary of applicable numeric temperature targets in the Willamette Subbasins.

Applicable Criteria	Fish and Aquatic Life Use Protected	7DADM Temperature Target (°C)	Notes
Biologically based numeric criteria apply OAR 340-041-0028(4) or Protecting colder water criterion OAR 340-041-0028(11)	Waters that exceed the biologically based numeric criteria		
	Salmon and steelhead spawning	13.0 + 0.3 HUA	Seasonally applies
	Bull trout spawning and juvenile rearing	12.0 + 0.3 HUA	
	Core cold water habitat	16.0 + 0.3 HUA	
	Salmon and trout rearing and migration	18.0 + 0.3 HUA	
	Salmon and steelhead migration corridor	20.0 + 0.3 HUA	
	Waters that are always colder than the applicable biologically based numeric criteria and the protecting colder water criterion does not apply		
	Salmon and steelhead spawning	13.0	Seasonally applies
	Core cold water habitat	16.0	
	Salmon and trout rearing and migration	18.0	
	Salmon and steelhead migration corridor	20.0	
	Waters that are always colder than the applicable biologically based numeric criteria and the protecting colder water criterion applies		
	Fish and aquatic life	Ambient temperature + 0.3 HUA	

Bull trout spawning narrative OAR 340-041-0028(4){f}	Bull trout spawning and juvenile rearing use McKenzie River	Ambient temperature + 0.3 HUA when the ambient is ≥ 9.0	August 15 - May 15
		Ambient temperature + 1.0 HUA when the ambient < 9.0	
Coldwater refugia narrative OAR 340-041-0028(4)(d)	Salmon and steelhead migration corridor cold water refuges	2 degrees Celsius colder than the daily maximum temperature of the adjacent well-mixed water body	Cold water refugia must be sufficiently distributed. See cold water refugia narrative interpretation study (DEQ, 2020).
Cool Water Species OAR 340-041-0028(9)	Cool water species Long Tom River	24.0 + 0.3 HUA	June 15 – October 31
		18.0 + 0.3 HUA	November 1 – June 14
	Cool water species Rickreall Creek	22.8 + 0.3 HUA	June 1 – September 30
		18.0 + 0.3 HUA	October 1 – May 31
Natural lakes narrative OAR 340-041-0028(6)	Fish and aquatic life Natural Lakes	Natural thermal condition + 0.3 HUA as a 7DADM	Absent a discharge or human modification that would reasonably be expected to increase temperature, DEQ will presume that the ambient temperature of a natural lake is the same as its natural thermal condition

5 Seasonal variation and critical period for temperature

Per OAR 340-042-0040(4)(j) and 40 Code of Federal Regulation 130.7(c)(1), TMDLs must also identify any seasonal variation and the critical condition or period of each pollutant, if applicable.

Maximum 7DADM stream temperatures typically occur in July or August. July and August are months when stream flows typically are low, solar radiation fluxes are high, and ambient air temperature conditions are warmest. Maximum 7DADM temperatures downstream of some large dam and reservoir operations are shifted from July and August to September, October, and November.

The critical period is based on the frequency and period when 7DADM stream temperatures exceed the applicable temperature criteria. DEQ uses the critical period to determine when allocations apply. In setting this period, DEQ relied upon monitoring sites with the longest period of exceedance and frequency of exceedance. When downstream monitoring sites have longer exceedance periods relative to upstream waters, the longer period is used as the critical period for upstream waterbodies when the downstream waterbodies were not modeled; or if the model shows thermal loads to upstream waterbodies contribute to temperature criteria exceedances in downstream waterbodies. For example, the period of exceedance for the lower McKenzie River

based on temperature data from the lower McKenzie River is May 1 to October 31 (TSD Section 5). However, the period of exceedance for the Willamette River downstream from the confluence of the McKenzie River is April 1 to November 15. Since lower McKenzie River point sources, including IP Springfield, contribute to temperature criteria exceedances in the Willamette River, the McKenzie River critical period for which WLAs apply is set to April 1 to November 15. This ensures warming of upstream waters does not contribute to downstream exceedances.

The critical periods for waterbodies in the Willamette Subbasins are presented in **Table 5-1**. Allocations presented in the TMDL apply during these periods. Section 5 of the TSD summarizes the critical period approach and presents plots of 7DADM temperature data used to determine seasonal variation and the critical periods.

Table 5-1: Designated critical periods for waters in the Willamette Subbasins.

Subbasin	Watershed or Waterbody Name	Critical Period
Middle Fork Willamette Subbasin 17090001	All waters, except those noted	May 1 – October 31
	Middle Fork Willamette River from Hills Creek Dam to North Fork Middle Fork Willamette River OR_SR_1709000105_02_104580 OR_SR_1709000105_02_103720	May 1 – November 30

6 Temperature water quality data evaluation overview

A critical TMDL element is water quality data evaluation and analysis to the extent that existing data allow. To understand the water quality impairment, quantify the loading capacity, identify pollutant sources, and assess various management scenarios that achieve the TMDL and applicable water quality standards, the analysis requires a predictive component. Certain models provide a means to evaluate potential stream warming sources and, to the extent existing data allow, their current and potential pollutant loads. Heat Source and CE-QUAL-W2 temperature models were used in this effort and are described in the TSD model appendices.

The modeling framework needs for this project included the abilities to predict or evaluate the following on an hourly basis:

1. Stream temperatures spanning months at ≤ 500 m longitudinal resolution.
2. Solar radiation fluxes and effective shade at ≤ 100 m longitudinal resolution.
3. Stream temperature responses due to changes in:
 - a. Streamside vegetation,
 - b. Water withdrawals and upstream tributaries' stream flow,
 - c. Channel morphology in the upstream catchment, and
 - d. Effluent temperature and flow discharge from NPDES permitted facilities.

Figure 6-1 provides an overview of the analyses completed for this TMDL.

Figure 6-1: Willamette Subbasins temperature analysis overview.

7 Pollutant sources or source categories

As noted in OAR 340-042-0040(4)(f) and OAR 340-042-0030(12), a source is any process, practice, activity or resulting condition that causes or may cause pollution or the introduction of pollutants to a waterbody. This section identifies the various pollutant sources and estimates, to the extent existing data allow, the significance of pollutant loading from existing sources.

Both point and nonpoint sources are sources of thermal pollution to surface waters in the Willamette Subbasins. Within the nonpoint source category, both background and anthropogenic nonpoint sources contribute thermal pollution. Each source's thermal loading varies in frequency and magnitude based on the flow rate and temperature of discharge, prevalence of the activities, size of the land area on which the activities occur, locations of activities in relation to surface water, and transport mechanisms.

7.1 Thermal point sources

OAR 340-045-0010(17) defines a point source as "any discernible, confined and discrete conveyance, including but not limited to any pipe, ditch, channel, tunnel, conduit, well, discrete fissure, container, rolling stock, concentrated animal feeding operation, or vessel or other floating craft, from which pollutants are or may be discharged."

Individual and some general NPDES permittees were identified as sources of thermal loading to waters in the Willamette Subbasins and assigned thermal waste load allocations. While individual and some general NPDES permittees identified in this TMDL discharge or have potential to discharge thermal loads that increase stream temperature, the loading from the majority of the individual facilities evaluated do not result in temperature increases that exceed the 0.30°C human use allowance.

7.1.1 Individual NPDES permitted point sources

There are 113 domestic or industrial facilities with an individual NPDES permit within the Willamette Subbasins. In addition, there are 8 facilities that have submitted individual NPDES permit applications for discharge to waters in the Willamette Subbasins. 112 of the permitted facilities and all 8 of the facilities with pending permits were identified as potential sources of thermal load (**Table 7-1**). There also are 7 individual Municipal Separate Storm Sewer System (MS4 Phase I and Phase II) NPDES permits covering 21 permittees (**Table 7-3**).

The point sources covered by individual NPDES permits identified in **Table 7-2** discharge stormwater only or have a stormwater only outfall. DEQ determined that these stormwater discharges and those covered under the MS4 stormwater permits (**Table 7-3**) do not have potential to discharge thermal loads that contribute to exceedances of applicable temperature criteria. Therefore, no additional TMDL requirements are needed for the stormwater sources to control temperature, other than those included in the current individual NPDES permits. More specific thermal wasteload allocations can be considered if subsequent data and evaluation demonstrates a need and if reserve capacity is available. Note that numeric thermal WLAs have been provided to Arkema and Jasper Wood Products for non-stormwater discharges that may contribute to exceedances of applicable temperature criteria, including process water, boiler condensate, and non-contact cooling water.

Table 7-1: Individual NPDES permitted point source discharges that have the potential to contribute thermal loads to Willamette Subbasins streams at a frequency and magnitude to cause exceedances to the temperature standard.

7.1.2 General NPDES permitted point sources

There are multiple categories of general NPDES permit types with registrants in the Willamette Subbasins, including:

- 100-J Industrial Wastewater: NPDES cooling water (GEN01)
- 200-J Industrial Wastewater: NPDES filter backwash (GEN02)
- 300-J Industrial Wastewater: NPDES fish hatcheries (GEN03)
- 400-J Industrial Wastewater: NPDES log ponds (GEN04)
- 500-J Industrial Wastewater: NPDES boiler blowdown (GEN05)
- 700-PM Industrial Wastewater: NPDES suction dredges (GEN07PM)
- 1200-A Stormwater: NPDES sand & gravel mining (GEN12A)
- 1200-C and 1200-CA - Stormwater: NPDES construction more than 1 acre disturbed ground (GEN12C and GEN12CA)
- 1200-Z Stormwater: NPDES specific SIC codes (GEN12Z)
- 1500-A Industrial Wastewater: NPDES petroleum hydrocarbon cleanup (GEN15Z)
- 1700-A Industrial Wastewater: NPDES wash water (GEN17A)
- 2000-J and 2300-A Pesticide application (GEN20 and GEN23)
- CAFO Confined Animal Feeding Operations
- MS4 – Phase II – Stormwater: NPDES Municipal Separate Storm Sewer System (GEN40)

DEQ determined the following general permit categories have potential to discharge thermal loads that contribute to exceedances of the applicable temperature criteria:

- 100-J Industrial Wastewater: NPDES cooling water
- 200-J Industrial Wastewater: NPDES filter backwash
- 300-J Industrial Wastewater: NPDES fish hatcheries

There are twenty registrants of the 100-J, eleven registrants of the 200-J, and four registrants of the 300-J general permits (**Table 7-4**) found to be potential significant sources of thermal load with a temperature impact. Wasteload allocations for these registrants are provided in Section 9.1. Not all registrants to the 200-J were found to be a significant source. DEQ's analysis is documented in TSD Section 7.1.2.2.

DEQ has received multiple 200-J general permit applications from facilities seeking coverage under that permit. Action on these applications are awaiting 200-J permit renewal. Should it be determined by DEQ that discharges from these facilities have reasonable potential to increase temperatures above the applicable criteria, reserve capacity may be assigned as appropriate.

Other registrants to the industrial wastewater, stormwater, and other general permits will not contribute to exceedances of applicable temperature criteria and impact beneficial uses based on the permit requirements, available dilution, or frequency and magnitude of discharge (see TSD Section 7.1). Therefore, no additional TMDL requirements are needed to control temperature, other than those included in the current NPDES permits. More specific wasteload allocations can be considered if subsequent data and evaluation demonstrates a need and if reserve capacity is available.

Table 7-4: General NPDES permit registrants that have the potential to contribute thermal loads to Willamette Subbasins streams at a frequency and magnitude to cause exceedances to the temperature standard.

7.2 Thermal nonpoint sources

OAR 340-041-0002(42) defines nonpoint sources as “diffuse or unconfined sources of pollution where wastes can either enter, or be conveyed by the movement of water, into waters of the state.” Nonpoint sources of heat in the Willamette Subbasins streams include activities associated with agriculture, forestry, dam and reservoir management, and development.

Nonpoint sources or activities that contribute thermal load and may increase stream temperature include:

- Human caused increases in solar radiation loading to the stream network from the disturbance or removal of near-stream vegetation;
- Channel modification and widening;
- Dam and reservoir operation;
- Activities that modify flow rate or volume; and
- Background sources, including natural sources and anthropogenic sources of warming through climate change and other factors.

Anthropogenically influenced thermal loads are targeted for reduction to attain the temperature water quality criteria. The following actions are needed to attain the TMDL allocations:

- Restoration of streamside vegetation to reduce thermal loading from exposure to solar radiation;
- Restoration of complex channel morphology and hyporheic or groundwater connection;
- Management and operation of dams and reservoirs to minimize temperature warming; and
- Maintenance of minimum instream flows.

In many of the modeled streams, thermal loading from nonpoint sources contributed to exceedances of the applicable temperature criteria and therefore were identified as significant sources of thermal loading. The maximum daily maximum or 7DADM water temperature

increase from nonpoint sources ranged from 0.43°C in the Upper McKenzie River to 8.65°C in the Pudding River. See the TSD for details. Reductions from nonpoint sources will be required to attain the applicable temperature criteria.

7.3 Thermal background sources

By definition (OAR 340-042-0030(1)), background sources include all sources of pollution or pollutants not originating from human activities. Background sources may also include anthropogenic sources of a pollutant that DEQ or another Oregon state agency does not have the authority to regulate, such as pollutants emanating from another state, tribal lands, or sources otherwise beyond the jurisdiction of the state.

The amount of background thermal loading a stream receives is influenced by a number of landscape and meteorological characteristics, such as substrate and channel morphology conditions; streambank and channel elevations; near-stream vegetation; groundwater; hyporheic flow; tributary inflows; precipitation; cloudiness; air temperature; relative humidity; and others. Many of these factors, however, are influenced by anthropogenic impacts related to the surrogate measures. As such, it was not possible to develop a model in which all human influences were controlled or accounted for. As a best estimate, background thermal sources were quantified for the modeled rivers with delineable anthropogenic influences (i.e., dams and reservoirs, vegetation alterations, point source discharges, channel modification) accounted for, thus isolating the remaining background sources.

In many of the modeled streams, thermal loading from background sources contributed to exceedances of the applicable temperature criteria and therefore were identified as significant source of thermal loading. The maximum daily maximum or 7DADM temperature standard exceedances of background sources ranged from 1.81°C in the South Fork McKenzie River to 9.32°C in the South Santiam River. Background sources from all but one of the 24 modeled streams exceeded the applicable temperature criteria. 15 of the 24 modeled streams exceeded the applicable temperature criteria by more than 7°C. See the TSD for detailed descriptions of analysis and results. Reductions from background sources will be required to attain the applicable temperature criteria.

8 Loading capacity and excess loads

Summarizing OAR 340-042-0040(4)(d) and 40 CFR 130.2(f), loading capacity is the amount of a pollutant or pollutants that a waterbody can receive and still meet water quality standards.

For temperature, thermal loading capacity is calculated on AUs using **Equation 8-1**.

$$LC = (T_C + HUA) \cdot Q_R \cdot C_F \quad \text{Equation 8-1}$$

where,

LC = Loading Capacity (kilocalories/day).

T_C = The applicable river temperature criterion (°C).

HUA = The 0.3°C human use allowance allocated to point sources, nonpoint sources, margin of safety, or reserve capacity.

Q_R = The daily mean river flow rate in cubic feet per second (cfs). For a lake, a dilution factor of 1 may be used for Q_R unless determined using another method.

C_F = Conversion factor using flow in cfs: 2,446,665

$$\left(\frac{1 \text{ m}}{3.2808 \text{ ft}} \right)^3 \cdot \frac{1000 \text{ kg}}{1 \text{ m}^3} \cdot \frac{86400 \text{ sec}}{1 \text{ day}} \cdot \frac{1 \text{ kcal}}{1 \text{ kg} \cdot 1^\circ\text{C}} = 2,446,665$$

Equation 8-1 shall be used to calculate the thermal loading capacity for any surface water location in the Willamette Subbasins. **Table 8-1** presents the loading capacity for select temperature impaired Category 5 AUs modeled for the TMDL analysis at the critical 7Q10 low flow. **Equation 8-1** may be used to calculate the loading capacity when river flows are greater than 7Q10. **Equation 8-1** may also be used to calculate the loading capacity if in the future the applicable temperature criteria are updated and approved by EPA.

Table 8-1: Thermal loading capacity (LC) for select AUs by applicable fish use period at 7Q10 flow.

In accordance with OAR 340-042-0040(4)(e), the excess load calculation evaluates, to the extent existing data allow, the difference between the actual pollutant load in a waterbody and the loading capacity of that waterbody.

Because flow monitoring data were not available at most temperature monitoring locations, it was not possible to calculate the excess load. Instead, the excess temperatures and percent load reduction were calculated for each AU where temperature data were available (**Table 8-2**). The extensive monitoring across the Willamette subbasin represents a wide range of waterbodies; however not all streams in the Willamette subbasins have monitoring data. Equation 8-2 from the TSD can be used to determine excess temperature and percent reduction for additional streams if data becomes available in the future.

$$PR = \frac{(T_R - T_C - HUA)}{T_R} \cdot 100 \quad \text{Equation 8-2}$$

where,

PR = Percent load reduction (%). If PR < 0, PR = 0

T_R = The maximum 7DADM ambient river temperature (°C).

T_C = The applicable river temperature criterion (°C).

HUA = The 0.3°C human use allowance assigned to point sources, nonpoint sources, margin of safety, or reserve capacity.

The excess temperatures are the maximum difference between the monitored 7DADM river temperatures and applicable numeric criteria plus the HUA. The percent load reduction represents the portion of the actual thermal loading that must be reduced to attain the TMDL loading capacity. The percent load reduction can be calculated from the excess temperature.

Table 8-2: Excess temperature and percent load reduction for AUs with available temperature data in the Middle Fork Willamette Subbasin (17090001).

9 Allocations, reserve capacity, and margin of safety

OAR 340-042-0040(4)(g),(h),(i) and (k) [and 40 CFR 130.2(h) and (g) and 130.7(c)(2)] respectively define the required TMDL elements of apportionment of the allowable pollutant load: point source wasteload allocations; nonpoint source load allocations (including background); margin of safety; and reserve capacity. Collectively, these elements add up to the maximum load of a pollutant that still allows a waterbody to meet water quality standards. OAR 304-042-0040(5) and (6) describe the potential factors of consideration for determining and distributing these allocations of the allowable pollutant loading capacities. Water quality data analysis must be conducted to determine allocations, potentially including statistical analysis and mathematical modeling. Factors to consider in allocation distribution may include: source contributions; costs of implementing management measures; ease of implementation; timelines for attaining water quality standards; environmental impacts of allocations; unintended consequences; reasonable assurance of implementation; and any other relevant factor.

9.1 Thermal allocations

9.1.1 Human use allowance assignments

The HUA at OAR 340-041-0028(12)(b)(B) identifies the allowed temperature increase reserved for human uses. The rule requires that wasteload and load allocations restrict all NPDES point sources and nonpoint sources to a cumulative increase of no greater than 0.3°C (0.5°F) above the applicable criteria after complete mixing in the waterbody, and at the POMI.

Table 9-1 through **Table 9-11** present the portions of the HUA assigned to anthropogenic source categories across different AUs and stream extents in the Willamette Subbasins. Temperature impacts associated with climate change sources are assigned a zero HUA. See TSD Section 9 for approach to HUA assignments.

The dam and reservoir operations source category accounts for nonpoint source temperature impacts associated with the dam impoundment and release of the impounded water back into the natural channel. Dam and reservoir discharges associated with an NPDES permit are included in the NPDES assigned HUA.

The water management activities and water withdrawals source category accounts for nonpoint source temperature impacts associated with the withdrawal of water that is intended for consumptive uses (such as irrigation) and the warming that might occur as that water moves through a canal or ditch before being returned to the natural river.

The assigned HUA for NPDES point sources is the maximum cumulative warming allowed anywhere in the AU from all NPDES individual permittees and registrants to general NPDES permits. The HUA assigned to any single NPDES point source is summarized in **Table 9-12**. Similarly, the assigned portion of the HUA for nonpoint sources represents the maximum cumulative warming allowed anywhere in the AU and stream extents at the POMI from all nonpoint source activities within each source category. Therefore, DEQ expects the amount of warming for each unique point or nonpoint source activity to be less than the values shown in **Table 9-1** through **Table 9-11**. DEQ will implement the TMDL in a manner consistent with the HUA rule by requiring all nonpoint sources to implement management strategies and reduce their warming impact such that the assigned HUA is attained. Point sources will be required to implement their wasteload allocations through their NPDES permits such that the assigned HUA is attained.

The HUA assignments in **Table 9-1** through **Table 9-11** for nonpoint source categories are achieved through the implementation of the load allocations described in Section 9.1.4 and the surrogate measures described in Section 9.1.5. Designated Management Agencies (DMAs) are responsible for implementing management activities that achieve the surrogate measure targets appropriate to their source category and location. A DMA has achieved their load allocation when surrogate measure targets are met. When all DMAs within a nonpoint source category have met their surrogate measure targets and achieved their load allocations, the HUA assigned to that nonpoint source category is achieved.

This TMDL HUA assignments and associated allocations implement EPA's Columbia and Lower Snake Rivers temperature TMDL (EPA, 2021) allocation to anthropogenic sources in Columbia River tributaries, including the Willamette River. See TSD Appendix M for additional details.

a: PGE Willamette Falls and River Mill Dam b: 0.01 of HUA is attributed to a portion of warming in the Willamette River from tributary sources. See TSD Appendix M for details.								

9.1.2 Thermal wasteload allocations for point sources

Wasteload allocations are assigned to NPDES permitted point sources listed in **Table 9-12**. Discharges covered by a number of NPDES permits have been determined to be unlikely to contribute to exceedances of temperature criteria. The wasteload allocation for the Phase I individual MS4 stormwater permits, individually permitted stormwater discharges from Portland International Airport (DEQ file number 107220, EPA number OR0040291), Jasper Wood Products, LLC outfall 002 (DEQ file number 10009, EPA number OR0042994) and Arkema, Inc. outfalls 001-004 (DEQ file number 68471, EPA number OR0001597), registrants under the general stormwater permits (MS4 phase II, 1200-A, 1200-C, 1200-CA and 1200-Z), and registrants under 400-J, 1500-A, and 1700-A general permits are set equal to loads permitted by the applicable NPDES permit. This means that individual permittees and registrants must follow their permit conditions to meet the wasteload allocation. Beyond NPDES permit limits, no additional TMDL requirements are needed for these sources to control temperature. For all general wastewater and stormwater NPDES permits, more precise wasteload allocations may be considered if subsequent data analysis indicates a need and loading capacity is available.

Wasteload allocations were calculated using **Equation 9-1**.

$$WLA = \Delta T \cdot (Q_E + Q_R) \cdot C_F$$

Equation 9-1a

$$WLA = \Delta T \cdot Q_E \cdot D_F \cdot C_F$$

Equation 9-1b

where,

WLA = Wasteload allocation (kilocalories/day), expressed as a rolling seven-day average.

ΔT = The assigned portion of the HUA from **Table 9-12**. It is the maximum temperature increase (°C) above the applicable river temperature criterion using 100% of river flow not to be exceeded by each individual source from all outfalls combined. When the minimum duties provision at OAR 340-041-0028(12)(a) applies, $\Delta T = 0.0$. See **Table 9-13** for list of NPDES permittees where minimum duties provision may apply.

Q_E = The daily mean effluent flow (cfs).
When effluent flow is in million gallons per day (MGD) convert to cfs:

$$\frac{1,000,000 \text{ gallons}}{1 \text{ day}} \cdot \frac{0.13368 \text{ ft}^3}{1 \text{ gallon}} \cdot \frac{1 \text{ day}}{86,400 \text{ sec}} = 1.5472 \text{ ft}^3/\text{sec}$$

Q_R = The daily mean river flow rate, upstream (cfs).
When river flow is $\leq 7Q_{10}$, $Q_R = 7Q_{10}$. When river flow $> 7Q_{10}$, Q_R is equal to the daily mean river flow, upstream.

D_F = Dilution factor. $(Q_E + Q_R)/Q_E$ For lakes, the dilution factor is 1 unless determined using another method.

C_F = Conversion factor using flow in cfs: 2,446,665

$$\left(\frac{1 \text{ m}}{3.2808 \text{ ft}} \right)^3 \cdot \frac{1000 \text{ kg}}{1 \text{ m}^3} \cdot \frac{86400 \text{ sec}}{1 \text{ day}} \cdot \frac{1 \text{ kcal}}{1 \text{ kg} \cdot 1^\circ\text{C}} = 2,446,665$$

The effluent discharge used to calculate the wasteload allocations presented in **Table 9-12** are based on the average dry weather facility design, a maximum discharge authorized by an NPDES permit, or an effluent discharge characterized from discharge data. More information on the specific source of the effluent discharge flow and the rationale behind the assigned HUA is

described in the TSD Section 9.2, or TSD Appendix M for NPDES permittees discharging to the mainstem Willamette River and major tributaries.

Wasteload allocations may be implemented in NPDES permits in any of the following ways:

- (1) Incorporate the 7Q10 wasteload allocation in **Table 9-12** as a static numeric limit. Permit writers may recalculate the static limit using different values for 7Q10 (Q_R) and effluent discharge (Q_E) using seasonal values or annual values, as appropriate, if more recent data or better estimates are available.
- (2) Incorporate **Equation 9-1** directly into the permit with effluent flow (Q_E), river flow (Q_R), and the wasteload allocation (WLA) being dynamic and calculated on a daily basis. The assigned portion of the HUA (ΔT) is static and based on the value in **Table 9-12**. Permit writers may recalculate the 7Q10 using seasonal or annual values, as appropriate, if more recent data or better estimates are available.

The wasteload allocation period for each facility is consistent with the critical period of the receiving waterbody, which is presented in Section 5: Seasonal variation and critical period for temperature. Wasteload allocations in **Table 9-12** for facilities currently enrolled as a registrant under a general permit may be incorporated into an individual permit, if the facility obtains an individual permit for the same discharge in the future.

Table 9-12: Thermal wasteload allocations (WLA) for point sources.

¹ Listed WLAs were calculated based on the 7Q10 flow.

² ATI Millersburg and Albany-Millersburg Water Reclamation Facility discharge to the same outfall, but each holds an individual NPDES permit and is assigned its own thermal WLA. These two WLAs may either be addressed individually with the facilities' permits or may be combined as the sum of the two WLAs and addressed as a single WLA.

³ 7Q10 not calculated due to lack of flow data and tidal influence. HUA not assigned. Model shows 2015 maximum impacts of all point sources in Multnomah Channel ≤ 0.09 C. WLA represents a total thermal load calculated as $WLA = A_F * Q_E * (T_E - T_C) * C_F$, where $A_F = 1.3$ (adjustment factor), $T_E = 25.0^\circ\text{C}$ (effluent temperature), $T_C = 18$ (the applicable temperature criteria), $Q_E = 0.9$ cfs (average dry weather design flow), and C_F = a conversion factor to produce WLA in kcal/day.

Notes:

WLA = wasteload allocation; kcal/day = kilocalories/day

* When the minimum duties provision at OAR 340-041-0028(12)(a) applies, $\Delta T = 0.0$ and the WLA = 0 kilocalories/day.

** Listed 7Q10s calculated based on a seasonal period corresponding to WLA period.

The minimum duties provision at OAR 340-041-0028(12)(a) states that anthropogenic sources are only responsible for controlling the thermal effects of their own discharge or activity in accordance with its overall heat contribution.

For point sources, DEQ is implementing the minimum duties provision if a facility operation meets acceptable operation and design requirements. The facility must be operated as a “flow through” facility where intake water moves through the facility and is not processed as part of an industrial or wastewater treatment operation. If a facility mixes the intake water with other wastewater or as a method to cool equipment DEQ considers the thermal effects of this operation to be part of the facility’s own activity and the minimum duties provision does not apply. The intake water must also be returned to the same stream where the intake is located. If the water is not returned to the same stream the thermal effects do not originate from the receiving stream and therefore are considered as part of the facilities own discharge.

When the minimum duties provision applies, the facility cannot add any additional thermal loading to the intake temperatures when the intake temperatures are warmer than the maximum effluent discharge temperatures allowed by the wasteload allocation. The purpose is to ensure the facility controls for thermal effects resulting from passing the water through and not from upstream sources. The specific equations to implement this approach in NPDES permits are included in the TSD Section 9.2.2 through Section 9.2.9. DEQ determined the minimum duties provision is applicable to the facilities listed in **Table 9-13**.

Table 9-13: NPDES permittees where the minimum duties provision may be implemented as part of the TMDL wasteload allocation.

9.1.3 Thermal wasteload allocations for 100-J general permit registrants

The TMDL includes WLA requirements for registrants to the 100-J general permit. The WLA for current and future registrants to the 100-J general permit is equal to loads permitted by the 100-J general permit and the TMDL requirements identified in **Table 9-14** and **Table 9-15**. See TSD section 9.2.3 for additional information and background.

Table 9-14: Assigned HUA and TMDL requirements for 100-J permit registrants in the Willamette Subbasins.

9.1.4 Thermal load allocations for nonpoint sources

Load allocations are assigned to background sources and anthropogenic nonpoint sources on all waters, as defined in Section 2, in the Willamette Subbasins.

The allocation period is consistent with the critical period of each waterbody, which is presented in Section 5: Seasonal variation and critical period for temperature.

Load allocations for background sources are calculated using **Equation 9-2**.

$$LA_{BG} = (T_C) \cdot (Q_R) \cdot C_F$$

Equation 9-2

where,

LA_{BG} = Load allocation to background sources (kilocalories/day), expressed as a rolling seven-day average.

T_C = The applicable temperature criteria, not including the HUA. When there are two year-round applicable temperature criteria that apply to the same AU, the more stringent criteria shall be used.

Q_R = The daily average river flow rate (cfs). For a lake, a dilution factor of 1 may be used for Q_R unless determined using another method.

C_F = Conversion factor using flow in cfs: 2,446,665

$$\left(\frac{1 \text{ m}}{3.2808 \text{ ft}} \right)^3 \cdot \frac{1 \text{ m}^3}{35.31 \text{ ft}^3} \cdot \frac{1000 \text{ kg}}{1 \text{ m}^3} \cdot \frac{86400 \text{ sec}}{1 \text{ day}} \cdot \frac{1 \text{ kcal}}{1 \text{ kg} \cdot 1^\circ\text{C}} = 2,446,665$$

Table 9-16 presents the load allocations assigned to background sources on temperature impaired Category 5 AUs that were modeled for the TMDL analysis. The load allocations are based on the 7Q10 low river flows and the minimum applicable criterion in the respective AUs. **Equation 9-2** shall be used to calculate the load allocations assigned to background sources on all other AUs or stream location in the Willamette Subbasins not identified in **Table 9-16**; or for any AUs identified in **Table 9-16** when river flows are greater than 7Q10.

If the applicable temperature criteria are updated and approved by EPA, the background load allocations assigned to any AU or stream location where the temperature criterion changed shall be recalculated using the updated criterion and **Equation 9-2**.

Load allocations assigned to anthropogenic nonpoint sources on any AU or stream location in the Willamette Subbasins are calculated using **Equation 9-3**. The portions of the HUA (ΔT) assigned to nonpoint sources or source categories are presented in Section 9.1.1. When all of the load allocations assigned to a nonpoint source or source category have been achieved, the HUA allocation to that nonpoint source or source category is achieved.

$$LA_{NPS} = (\Delta T) \cdot (Q_R) \cdot C_F \quad \text{Equation 9-3}$$

where,

- LA_{NPS} = Load allocation to anthropogenic nonpoint sources (kilocalories/day), expressed as a rolling seven-day average.
- ΔT = The portion of the HUA assigned to each nonpoint source category representing the maximum cumulative temperature increase ($^{\circ}\text{C}$) from all source activity in the nonpoint source category. When the minimum duties provision at OAR 340-041-0028(12)(a) applies, $\Delta T = 0.0$.
- Q_R = The daily average river flow rate (cfs). For a lake, a dilution factor of 1 may be used for Q_R unless determined using another method.
- C_F = Conversion factor using flow in cfs: 2,446,665
- $$\left(\frac{1 \text{ m}}{3.2808 \text{ ft}} \right)^3 \cdot \frac{1 \text{ m}^3}{35.31 \text{ ft}^3} \cdot \frac{1000 \text{ kg}}{1 \text{ m}^3} \cdot \frac{86400 \text{ sec}}{1 \text{ day}} \cdot \frac{1 \text{ kcal}}{1 \text{ kg} \cdot 1^{\circ}\text{C}} = 2,446,665$$

9.1.5 Surrogate measures

EPA regulations (40 CFR 130.2(i)) and OAR 340-042-0040(O)(5)(b) allow for TMDLs to utilize other appropriate measures (or surrogate measures). This section presents surrogate measures that implement the load allocations.

9.1.5.1 Dam and reservoir operations

Dam and reservoir operations have been assigned a thermal load allocation as calculated using the assigned HUA from Table 9-1 through Table 9-11 using **Equation 9-3**. Monitoring stream temperature, rather than a thermal load, is easier and a more meaningful approach for reservoir management. Temperature is mathematically related to excess thermal loading and directly linked to the temperature water quality standard. For these reasons, DEQ is using a surrogate measure to implement the load allocation for dam and reservoir operations.

DEQ has developed the following surrogate measure temperature approach to implement the load allocation. The surrogate measure compliance point is located just downstream of the dam or just downstream of where impounded water is returned to the free-flowing stream. The surrogate measure is:

- a) Release temperatures less than or equal the 7DADM temperatures immediately upstream of the reservoirs. If multiple streams flow into the reservoir, 7DADM temperatures upstream of the reservoirs may be calculated as a flow weighted mean of temperatures from each inflowing tributary. The estimated free flowing (no dam) temperatures may be calculated using a mechanistic or empirical model to account for any warming or cooling that would occur through the reservoir reaches absent the dam and reservoir operations. The results may be applied as the temperature surrogate

measure or to adjust the 7DADM temperatures monitored immediately upstream of the reservoirs. Use of the model approach for the surrogate measure must be approved by DEQ.

- b) Additional adjustments to the surrogate temperature target calculated or measured under item a) may be allowed when all the following are true:
 - i. Monitoring data shows 7DADM temperatures do not exceed the applicable temperature criteria plus assigned HUA in the AU downstream of the dam;
 - ii. The protecting cold water criterion at OAR 340-041-0028(11) does not apply. DEQ has evaluated which dams the protecting cold water criterion likely apply in the TSD Section 9.4.1.1;
 - iii. A cumulative effects analysis, approved by DEQ, demonstrates that dam release water temperatures warmer than the surrogate measure calculated or measured under item a) will result in attainment of the dam and reservoir assigned HUA above the applicable criteria in downstream waters.

For implementation of the low flow conditions provision at OAR 340-041-0028(12)(d), the 7Q10 shall be calculated at a monitoring gage upstream of the reservoir or at nearby gage that isn't influenced by the dam's operations.

9.1.5.2 Site specific effective shade surrogate measure

Effective shade surrogate measure targets shown in **Table 9-17** and **Table 9-18** represent a surrogate for the amount of solar loading that will attain the HUA and load allocations for nonpoint sources managing streamside vegetation. The surrogate measure is the arithmetic mean of the effective shade values at all model nodes assigned to each DMA (**Equation 9-4**). **Equation 9-4** may be used to recalculate the mean effective shade targets if DMA boundaries change or the DMA boundary needs to be corrected. **Equation 9-4** may also be used to recalculate the mean effective shade targets based on an updated shade gap assessment following the process and methods outlined in the WQMP.

Changes in the target effective shade from the values presented in **Table 9-17** and **Table 9-18** may result in redistribution of the sector or source responsible for excess load reduction. If the shade target increases, the equivalent portion of the excess load is reassigned from background sources to nonpoint sources. If the shade target decreases, the portion of the excess load is reassigned from nonpoint sources to background sources. The exact portion reassigned can only be determined in locations where temperature models have been developed. In locations without temperature models, the reassignment remains unquantified. Changes to the target effective shade do not impact the loading capacity, HUA, or the load allocations. They remain the same as presented in this TMDL.

$$\overline{ES} = \frac{\sum ES_{n_i}}{n_i} \quad \text{Equation 9-4}$$

Where,

$\overline{ES}$ = The mean effective shade for DMA *i*.

$\sum ES_{n_i}$ = The sum of effective shade from all model nodes or measurement points assigned to DMA *i*.

n_i = Total number of model nodes or measurement points assigned to DMA *i*.

Table 9-17: Site specific effective shade surrogate measure targets to meet nonpoint source load allocations for specific model extents.

9.1.5.3 Effective shade curve surrogate measure

Effective shade surrogate measure targets represent a surrogate for the amount of solar loading that will attain the HUA and load allocations for nonpoint sources managing streamside vegetation. Effective shade curves are applicable to any stream that does not have site specific shade targets (Section 9.1.5.2). Effective shade curves represent the maximum possible effective shade for a given vegetation type. The values presented within the effective shade curves (**Figure 9-5** to **Figure 9-26**) represent the mean effective shade target for different mapping units, stream aspects, and active channel widths. The vegetation height, density, overhang, and buffer widths used for each mapping unit is summarized in **Table 9-19**. See the TSD Appendix A: Heat Source Model Report and Appendix C: Potential Near-Stream Land Cover for additional details on the model approach for shade curves and the methodologies

used to determine the mapping units and vegetation characteristics. Section 14 of this TMDL document provides tables of the plotted shade curve values. Links to a GIS map of all mapping units in the Willamette Basin can be found in the TSD Appendix H: Willamette Subbasins Interactive TMDL Map. This is an interactive HTML map that can be opened in an internet browser.

Local geology, geography, soils, climate, legacy impacts, natural disturbance rates, and other factors may prevent effective shade from reaching the target effective shade. No enforcement action will be taken by DEQ for reductions in effective shade caused by natural disturbances. Where natural disturbances prevent achievement of the target effective shade, DEQ will work with the DMAs to develop plans to restore riparian vegetation.

Table 9-19: Vegetation height, density, overhang, and horizontal distance buffer widths used to derive generalized effective shade curve targets for each mapping unit.

How to use a shade curve:

1. Determine the applicable mapping unit for the stream location you are applying a shade curve to.

Example: Your site of interest is in the Rickreall Creek watershed, in the City of Independence, along the west bank of a tributary to the Willamette River. Open the

Willamette Subbasins Interactive TMDL Map (TSD Appendix H) and select the Shade Curve Mapping Units Layer in the Map Legend to add it to the map. You may also want to select the City Boundaries Layer and the Stream Names Layer to help identify your site of interest. Once you have identified your site of interest, click that point on the map and you will see a pop-up box that identifies the Shade Curve Mapping Unit for that point. In this example, you identify the mapping unit at your site to be Qalc (Quaternary alluvium floodplain deposits) (**Figure 9-3**).

Figure 9-3: Mapping units in the example area of interest from the Willamette Subbasins Interactive TMDL Map.

- Determine the stream aspect from north.

Example: Standing in-stream mid-channel, facing north you determine the river's aspect as 0° or 180° from north (this means the river reach runs south to north).

- Determine the active channel width of the stream reach.

Example: At your location you measure the active channel width using a tape measure or laser range finder and determine that it is 25 ft.

- Use the appropriate mapping unit shade curve, stream aspect line, and active channel width (x-axis), to determine the percent effective shade of your site (y-axis). This is the surrogate measure effective shade target of that stream reach location.

Example: You have determined that the appropriate shade curve mapping unit for your site is Qalc (**Figure 9-4**). Since you are located on a tributary with an East-West stream aspect and an active channel width of 25 ft, you use the dotted line to determine the effective shade. By reading the y-axis, you determine that the effective shade to be ~83% when system potential vegetation is applied to the left and right bank of the stream reach. System potential vegetation defines the average riparian vegetation height as 88.2 ft (26.9 m), and the stand density (canopy density) as 71%.

9.1.6 Reserve capacity

DEQ set aside explicit portions of the HUA as reserve capacity that may be available to provide either point or nonpoint source allocation(s) to new or increased thermal loads, or to assign corrected allocations to any existing source(s) that were assigned an erroneous allocation or may not have been identified during the development of this TMDL. The portion of the HUA associated with the reserve capacity is described Section 9.1.1.

If DEQ determines the cumulative warming from all NPDES point sources is less than the assigned portion of the HUA, the remainder may be considered as reserve capacity for point sources.

Modeling analyses were performed to evaluate the impacts of wasteload and load allocations (WLAs and LAs) provided for the Willamette River and major tributaries as well as all tributaries to these reaches in order to ensure that cumulative impacts of WLAs and LAs do not exceed the 0.3°C HUA and to determine maximum amounts of the HUA that can be assigned as reserve capacity (see TSD Section 10.3). The analysis showed that for most AUs sufficient assimilative capacity is available to accommodate the reserve capacity summarized in human use allowance assignments tables (Table 9-1 to Table 9-11). However, for three Willamette River AUs from Champoeg Creek to the confluence with the Columbia River (RM 45-0), it was necessary to reduce reserve capacity by 0.01°C to account for cumulative impacts of assigned WLAs and LAs, including the LAs provided to the PGE Clackamas River and PGE Willamette Falls projects. Similarly, reserve capacity on the Row River AU downstream of Dorena Reservoir (OR_SR_1709000202_02_103779) was reduced by 0.04 °C due to cumulative impacts from assigned WLAs and LAs.

DEQ will consider requests for allocation of reserve capacity submitted in writing on a case-by-case basis. Except when DEQ is correcting an error or omission, DEQ may require requesters to demonstrate that there are no reasonable alternatives to an increased load and to prepare modeling or similar analysis to ensure that loading capacity is available at the discharge location(s) or in downstream waters. The HUA assigned to reserve capacity may not be available for allocation due to cumulative warming and points of maximum impact downstream. DEQ will use its discretion in making determinations on requests, based on the information available and priorities appropriate at the time of the request. DEQ will track allocation of reserve capacity over time and will not approve requests once reserve capacity is depleted. Allocations of reserve capacity must be approved by DEQ's Director or designee.

9.2 Margin of safety

CFR 130.7(c)(1) and OAR 340-042-0040(4)(i) require a TMDL to include a margin of safety. The margin of safety accounts for lack of knowledge or uncertainty. This may result from limited data; an incomplete understanding of the exact magnitude or quantity of thermal loading from various sources; or the actual effect controls will have on loading reductions and receiving water. The margin of safety is intended to account for such uncertainties in a manner that is conservative and will result in environmental protection. A margin of safety can be achieved through two approaches: (1) implicitly using conservative analytical assumptions to develop allocations, or (2) explicitly specifying a portion of the TMDL loading capacity as a margin of safety.

In the Willamette Subbasins, an implicit margin of safety was used in derivation of the allocations. The primary conservative assumptions include:

- Setting effluent flow rates at average dry weather design flow (ADWDF) or a maximum flow obtained from discharge monitoring reports (DMRs) for the model scenario assessing the wasteload allocations and for assessments of current thermal loading. It is rare that actual discharges from point sources will reach design flows and sustain that discharge for long periods of time.
- Setting point source effluent temperatures as high as 32°C for the model scenario assessing the wasteload allocations. On days when the current thermal load was less than the wasteload allocation, the maximum effluent temperatures were increased above the actual temperatures up to either 32°C or the effluent temperature that would fully utilize the wasteload allocation. Actual maximum effluent temperatures are unlikely to get this warm or be sustained over multiple days or weeks.
- The cumulative effects analysis applied the maximum assigned HUA to each source category to assess cumulative allocation attainment. The modeling shows the maximum allowed temperature increase is limited to one or two days and generally occurs less than 5% of the time. Additionally, the maximum temperature increase is geographically limited and focused to distinct locations. This means that a portion of the loading capacity reserved for human use will go unutilized most of the time. The cumulative effects analysis was performed for modeled reaches and is described in the TSD and modeling reports (TSD Appendices A, J, K, and M).
- Groundwater inflows were assumed to be zero in most models. Because groundwater directly cools stream temperatures via mixing, this means that actual instream temperatures would be lower than modeled temperatures anywhere that groundwater influences exist.
- On unmodeled streams, the sum of individual human use allocations (HUAs) was used to assess cumulative attainment across the entirety of a given AU. This method does not account for longitudinal instream heat dissipation downstream from each thermal source. Thus, the total thermal load and corresponding temperature increase is likely to result in a maximum temperature increase of less than 0.3°C.

10 Water quality management plan

As described in OAR 340-042-0040(4)(I)(A)-(O), an associated WQMP is a required element of a TMDL and must include the following components: (A) Condition assessment and problem description; (B) Goals and objectives; (C) Proposed management strategies design to meet the TMDL allocations; (D) Timeline for implementing management strategies; (E) Explanation of how TMDL implementation will attain water quality standards; (F) Timeline for attaining water quality standards; (G) Identification of persons, including DMAs, responsible for TMDL implementation; (H) Identification of existing implementation plans; (I) Schedule for submittal of implementation plans and revision triggers; (J) Description of reasonable assurance of TMDL implementation; (K) Plan to monitor and evaluate progress toward achieving TMDL allocations and water quality standards; (L) Plan for public involvement in TMDL implementation; (M) Description of planned efforts to maintain management strategies over time; (N) General

discussion of costs and funding for TMDL implementation; and (O) citation of legal authorities relating to TMDL implementation.

DEQ sought and considered input from various persons, including DMAs, responsible for TMDL implementation and other interested public and prepared the Willamette Subbasins WQMP as a stand-alone document. DEQ intends to propose the draft WQMP as an element of Temperature TMDLs for the Willamette Subbasins for adoption as rule by the EQC.

11 Reasonable assurance

OAR 340-042-0030(9) defines Reasonable Assurance as “a demonstration that a TMDL will be implemented by federal, state or local governments or individuals through regulatory or voluntary actions including management strategies or other controls.” OAR 340-042-0040(6)(g) states that “to establish reasonable assurance that the TMDL’s load allocations will be achieved requires determination that practices capable of reducing the specified pollutant load: (1) exist; (2) are technically feasible at a level required to meet allocations; and (3) have a high likelihood of implementation.” Likewise federal regulations (40 CFR § 130.2(i)) and EPA’s TMDL guidance describes that when a TMDL is developed for waters impaired by both point and nonpoint sources and WLAs are based on an assumption that NPS load reductions will occur, the TMDL must provide “reasonable assurances” that NPS control measures will achieve expected load reductions (EPA, 1991).

The Willamette Subbasins TMDLs were developed to address both point and nonpoint sources with TMDL load reductions set at a level estimated to attain the applicable temperature criteria with consideration of opportunities for effective measures to reduce those contributions. Reasonable assurance that Oregon’s three-point test is met, needed load reductions will be achieved for nonpoint sources, and that antidegradation requirements and narrative water quality criteria will be attained is based primarily on an accountability framework incorporated into the WQMP. The accountability framework includes identification of pollutant reduction strategies by source and activity, identification of persons and agencies responsible to implement the strategies, timelines and measurable objectives, tracking implementation progress and water quality conditions, and DEQ action when responsible persons or agencies fail to implement. Section 7 of the WQMP (Reasonable Assurance of Implementation) discuss this framework directly.

The WQMP also includes a general discussion of implementation costs and available funding programs, identification of state legal authorities that aid in implementation of management strategies, and DEQ’s adaptive management approach DMA implementation if sufficient progress towards TMDL attainment is not being made. The entirety of the WQMP and its execution along with the implementation plans of persons and agencies responsible for TMDL implementation represents reasonable assurance that NPS load reductions will be achieved.

12 Protection plan

The scope of these temperature TMDLs includes all waters of the state, including freshwater perennial and intermittent streams in the Willamette Subbasins. As such, these TMDLs also

serve as a “protection plan” to prevent impairment in waters currently attaining the applicable water quality standards or for unassessed waters. The protection of these unimpaired waters has watershed-wide benefits such as:

- Clarity and consistency for implementation of management strategies throughout the watershed;
- Proactively applying management strategies and protections to waters where data are not available for establishing listing status;
- Improving TMDL outcomes by maintaining or improving water quality in streams that are tributary to listed streams;
- Creating efficiencies between TMDL and protection plan implementation (including monitoring, evaluating progress, adaptive management, enforcement, and leveraging partner entities’ efforts); and
- Assisting with funding opportunities for implementation when grants require projects to be part of a larger watershed plan.

Protection plan core elements, as described in materials available on EPA’s webpage (EPA, 2023a, 2023b), are fulfilled by the statements and references to specific sections of the TMDLs, WQMP, and TSD in the subsections that follow. A full list of AUs where the protection plan applies is in the TSD Appendix D.

12.1 Identification of specific waters to be protected and risks to their condition

Appendix D of the TMDL TSD lists all the assessments units within the Willamette Subbasins and their 2022 Integrated Report assessment status. Those AUs with the status of Category 2 or Category 3 are included in the protection plan, along with any unassessed waters that may be found to be unimpaired for temperature in the future. The same sources and processes described in Section 7 that have caused temperature impairments to some reaches in the watershed also pose a risk to unimpaired waters.

12.2 Quantification of loads and activities expected to resist degradation

Monitoring stations that provided data used in the TMDLs analyses are shown in the TSD Appendix A, Section 2.1. Water temperature data, along with flow measurements were used to calculate loading capacities of the pollutants and surrogates within the watershed. Applicable loading capacities for any unimpaired stream can be calculated using **Equation 8-1**.

Similar to loading capacities, relevant HUA assignments for anthropogenic sources are shown in **Table 9-1** through **Table 9-11**. Loads for nonpoint sources are calculated using **Equation 9-2**.

The implementation of management practices specified in Sections 2 and 5 of the WQMP also protect against risks to unimpaired waters.

12.3 Timeframes for protection

Timelines for watershed-wide implementation of the TMDLs are described in Section 5 of the WQMP and estimated timelines for attainment of water quality standards in the impaired stream reaches are provided in Section 4 of the WQMP. DEQ's watershed-wide approach ensures that the TMDLs and the protection plan will be implemented in a prioritized manner over the same timeframe that will be required to demonstrate effectiveness of management strategies in reducing excess pollutant loads.

12.4 Measures of success

The WQMP describes in detail DEQ's approach to quantitative and qualitative measures of progress in attaining and maintaining water quality standards, which is applied watershed-wide. Section 6 of the WQMP discusses quantitative and qualitative evaluation of implementation of management strategies, development of a plan for periodic monitoring and an approach to adaptive management. Section 7 of the WQMP details the interconnected framework for accountability of implementation, including: engaging with sources; setting measurable objectives; evaluating progress; conducting enforcement; and tracking status and trends.
